VOLUME XXXII MARCH, 1942 NUMBER ONE

THE CONDITIONS OF EXPANSION[1]

By SUMNER H. SLICHTER

I

In 1940, output per man-hour in American nonagricultural industries was roughly double that of 1920. In few periods of history has capacity to produce goods grown more rapidly than in the last twenty years. The industrial research staffs of American business in 1940 were nine times as large as in 1920, and so also were expenditures on research. At no time in the country's history had its capacity to increase production been so great. And yet the community which possessed this unparalleled productive capacity to improve methods and products did not glory in its strength. It was perplexed and baffled. Instead of looking forward confidently to achieving ever rising standards of living, it dreaded the future. It asked whether investment opportunities were becoming permanently insufficient, whether the rules for achieving prosperity were undergoing fundamental changes, whether new conditions were making its economic institutions no longer workable.

This sense of doubt and inadequacy did not exist, in the United States at least, before 1929. It was created by the depression and by the disappointing recovery. The great national effort required by the war may prove to be precisely what is needed to restore the country's faith in its capacity to master great problems. Nevertheless, the task of winning the peace requires that we face frankly the questions raised by the depression and the disappointing recovery. Is it true that new conditions—the decline in geographical expansion, the drop in population growth, shifts in economic and political power, and changes in public policy—are radically altering the problem of maintaining employment, so that plans for the post-war world must envisage important changes in policies and institutions? The thesis of these remarks is that the answer to this question is a qualified Yes.

[1] Presidential address delivered at the Fifty-fourth Annual Meeting of the American Economic Association, New York City, December 29, 1941.

II

Since the questions under consideration were first raised in this country by the disappointing recovery from the depression, it is convenient to begin our survey by a brief examination of some of the circumstances affecting recovery.

Whatever may be the ultimate effects of the decline in geographical expansion or the drop in the growth of population, neither of these influences appears to explain the depression or the disappointing recovery. Of course, it would have helped had there been another Mississippi Valley to develop. But no sudden change occurred in the state of our natural resources between the twenties and the thirties. Furthermore, older and more developed countries experienced a milder depression and recovered more completely.[2] As for the spectacular drop in the rate of population growth between the twenties and the thirties, evidence is lacking that it produced either an unfavorable shift in the consumption function or an unfavorable change in the slope of the function. Indeed, the number of non-employed persons per member of the working force has shown no appreciable change in forty years.[3] The possibility that drop in the population growth might have retarded expansion by limiting the opportunity to widen capital is excluded partly by the fact that the increase in the number of families dropped only slightly, and partly by the large and persistent unemployment which characterized the period. As far as the labor supply was concerned, ample opportunity to widen capital existed.

III

To a considerable extent the depression and the unsatisfactory recovery are explained by conditions which do not reflect permanent changes in the economic environment. Failure of banks was probably the most important single influence in making the depression more severe in the United States than in most other countries. No one would contend, however, that the vulnerability of our banking system to depression was a necessary or permanent condition. The very severity of the depression and the bank failures which accompanied it were themselves major impediments to recovery. Consider their effect in diminishing the fortunes of thousands of local capitalists and in making these men reluctant to risk the remainder of their resources. Small local

[2] By 1936, when 20 out of 23 countries reporting industrial production to the League of Nations had surpassed the output of 1929, industrial production in the United States was still 7 per cent below 1929. This country was in twenty-first place out of 23 countries in recovery from 1929. The industrial production in the United Kingdom in 1936 was 15.8 per cent above 1929; in Sweden, 35.0 per cent; in Finland, 39.0 per cent; in Denmark, 30.0 per cent; in Hungary, 18.4 per cent.

[3] The number of non-employed for every gainfully employed worker has changed as follows: 1900, 2.61; 1910, 2.41; 1920, 2.54; 1930, 2.51; 1940, 2.50.

capitalists have always been an important dynamic influence in the economy.[4] The bank failures and other special circumstances were also largely responsible for the great amount of distress housing which hung over the market until 1937. This prolonged the depression in residential building long after the rest of the economy had revived. In the absence

[4] Some indirect evidence of the effect of the depression upon local capitalists is provided by the income tax returns. For example, if one compares the volume of income after taxes in 1931 and 1935, two years in which the national income was about 55 billion dollars, one finds that incomes of $25,000 or more in the former year totaled 1.9 billion dollars, and in the latter, 1.5 billion dollars, or 21.9 per cent less. (Imre de Vegh, "Savings, Investment, and Consumption," *Am. Econ. Rev.*, Suppl., vol. xxx, Feb., 1941, p. 238.) These figures do not allow for capital gains and losses. Since the year 1931 was one in which capital losses were large, the realized incomes of over $25,000 before capital losses in 1931 were undoubtedly considerably more than 1.9 billion dollars.

An impediment to recovery after 1933 that has been neglected is the scarcity of business savings. The principal source of venture capital always has been the plowed-back earnings of business enterprises. These have always been the spearhead of expansion, the prerequisite for drawing in funds from the outside. Although individual corporations were able to save, corporations as a whole had no savings in the entire period from 1929 to 1939. And between 1935 and 1938, dividend disbursements exceeded earnings by a billion a year.

Corporations failed to save in the main because during the twenties they had established high dividend rates which they were attempting to restore. The disbursements of dividends were encouraged in 1936 and 1937 by the undistributed profits tax. Of course, enterprises had depreciation allowances, but there were severe demands upon these because of the postponed maintenance from the worst years of the depression. Even when allowance is made for funds from depreciation allowances, the amounts available for reinvestment by corporations in 1935 and 1936 were far smaller than in 1923, when the national income was comparable in amount. In 1923, undistributed profits and depreciation of non-financial corporations were 5.3 billion dollars. In 1935 and 1936, undistributed profits, depreciation, and depletion were $2.0 billions and $2.7 billions respectively. (T.N.E.C., *Hearings,* Part 9, "Savings and Investment," p. 4039, Exhibit 582.)

An important aspect of plowed-back earnings is that they are venture capital. They increase the equity of the business owners. Plowed-back earnings must be regarded as an even more important dynamic influence than the investments of the well-to-do. In the five years, 1922 to 1927, for example, business savings were 13.4 billion dollars. (S. Kuznets, *National Income and Capital Formation,* 1919-1935, p. 24.) Income of persons receiving more than $25,000 a year (after the payment of federal income taxes) in the same period was 21.9 billion dollars. (Imre de Vegh, *loc. cit.*) If we assume that half of the incomes above $25,000 were saved, the investment-seeking funds from this source in the period 1922 to 1927, were not quite 11 billion dollars.

Many economists have regarded business savings as a deflationary influence. In periods of contraction they probably are. The view that they are always a deflationary influence overlooks the fact that expansion begins with the plowing back of earnings. This is a preliminary step to getting outside capital. This is why business savings constitute the spearhead of expansion. In order to judge the full effect of plowing back of earnings, one must allow for its contagious effect. An expansion or improvement by one competitor compels rivals to make investment in an attempt to hold their position. This involves a "multiplier" which is different from the consumption multiplier used by Keynes. The Keynesian multiplier is based upon the amount of additional consumption which will be induced by a given expansion of investment. The investment multiplier indicates the additional investment that will be directly induced by a given expansion of investment.

of this distress housing, building construction in the period 1934 to 1937 would undoubtedly have been two to three times the rate which prevailed. Since housing has always been the most important single outlet for investment-seeking funds, the persistence of the depression in housing was a main deterrent to recovery.[5]

But conditions of a more permanent nature have influenced the recovery. The depression produced, or at least greatly accelerated, shifts in economic and political power which are likely to be permanent and it enormously stimulated the making of economic policy by the government. These shifts in power and changes in public policy not only affected recovery from the depression, but altered the long-run problem of giving employment. It is important to examine their influence.

IV

On the whole, the shift in economic and political power impeded recovery. It did this in three principal ways. In the first place, the very fact that a great shift in power was going on created uncertainty concerning the long-term yield on capital and hence created an abnormal preference for short-term production plans. In this way, uncertainty narrowed investment opportunity and reduced temporarily the marginal return on capital.[6]

In the second place, the shift in economic power altered in many plants the control of managements over labor costs and increased the difficulty of converting a rise of output into profits. It is instructive to compare the revival of profits after 1934 with the revival after 1921—two years in which national income was about 50 billion dollars. In 1921, non-financial corporations had a deficit of 355 million dollars, in contrast with a profit of 884 million dollars in 1934. Between 1921 and 1923, a rise of the national income of 17.2 billion dollars to a level of 70 billion dollars produced a 5.5 billion-dollar gain in the profits of non-financial corporations. Between 1934 and 1937, a slightly larger

[5] Part of the difficulties in housing must be attributed to unsatisfactory financial instruments, particularly short-term second mortgages.

[6] The extent to which the shifting of economic power and the imposition of new responsibilities upon business caused short-term plans to be preferred to long-term plans is roughly indicated by comparing for the two periods 1922-29 and 1933-39 expenditures on equipment in relation to expenditures on plant. Since expenditures on equipment are in large measure for replacement and expenditures on plant are in the main for the enlargement of capacity, the change in the relation between the two roughly illustrates the change in the importance of expenditures on long-run plans in relation to expenditures on current needs. Between 1922 and 1929, 81.3 cents were spent by business enterprises on plant for every dollar spent on equipment; between 1933 and 1939, only 44.5 cents were spent on plant for every dollar spent on equipment. Between 1922 and 1929, expenditures on plant were 29,774 million dollars and on equipment 36,626 million dollars; between 1933 and 1939, expenditures on plant were 10,850 million dollars and on equipment 24,155 million dollars.

rise in the national income (21.1 billion dollars) to a level of 71.4 billion dollars produced a gain of 3 billion dollars in profits. When profits come hard, the disposition to venture is weak.

The lesser success of enterprises in converting a rise of business into profits after 1933 than after 1921 is explained by a variety of circumstances, but very largely by the movements of labor efficiency and wages. Physical productivity per man-hour grew twice as fast after 1921 as after 1933 or 1934, but wage rates went up twice as rapidly in the second period as in the first. These differences were not entirely compensated by price movements.[7]

V

During the period when shifts in economic power and public policy substantially reduced the attractiveness of long-range plans, government fiscal policy was developing in ways that greatly reduced the marginal efficiency of capital and especially diminished the attractiveness of ventures involving considerable uncertainty and risk. To begin with, a large deficit in the regular budget persisted undiminished, except for one year,

[7] Between 1921 and 1923, man-hour productivity in manufacturing increased 3.06 per cent per year as against 2.0 per cent between 1934 and 1937. In mineral industries it increased 7.1 per cent a year in the first period and 5.0 per cent in the second; in railroading, 4.3 per cent in the first period, and 3.8 per cent in the second. (S. Bell, *Productivity, Wages, and National Income,* pp. 269, 271, 274.) Hourly earnings in manufacturing increased 3.2 per cent between 1921 and 1923, according to the National Industrial Conference Board. Between 1934 and 1937, hourly earnings in manufacturing increased 15.7 per cent according to the U.S. Bureau of Labor Statistics, and 19.6 per cent according to the National Industrial Conference Board.

In some respects it is more satisfactory to compare the period 1921 to 1926 with the period 1933 to 1937. In the first period man-hour productivity in manufacturing increased 4.3 per cent a year as against 1.7 per cent in the second; in the mineral industries, it increased 8.0 per cent a year in the first period and 3.7 per cent in the second; in railroading, it increased 3.3 per cent per year in the first period and 3.0 per cent in the second. Between 1921 and 1926, hourly earnings in manufacturing rose 8.4 per cent; between 1933 and 1937, 40 per cent.

In the case of electric light and power, productivity per man-hour apparently increased more rapidly following 1933 than following 1921—6.9 per cent a year between 1933 and 1937, instead of 2.8 per cent a year as between 1921 and 1926. The actual difference was probably considerably less than the figures indicate because there was much more construction in the industry in 1926 than in 1937. Some of the construction is done by outside contractors whose employees are not counted as in the industry. Much of it, however, is done by employees of the utilities. As the construction is not counted as part of the product of the industry, the use of employees of the industry tends to reduce the output per man-hour. The changing proportion of employees working on non-current operations (together with the changing proportion engaged on maintenance and repairs as maintenance is now postponed and then accelerated) makes all figures on man-hour productivity more or less unreliable. In the case of comparisons between 1921-26 on the one hand, and 1933-37 on the other, the changes in construction and in maintenance policy probably cause the difference in increase in efficiency to appear to be less than it really was.

Finished goods declined relative to raw materials in both recoveries (as is usual)

in the face of a substantial rise in the national income and of large increases in taxes. Deficit financing is too new to be well understood. We are still in the stage of trying to find out why the course of events does not correspond to the theoretical models. Nevertheless, it is possible to see why deficit financing at the best is an unreliable device and why it may do little good and may even impede an expansion of privately produced income. Since the saving function is considerably more elastic relative to national income than the investment function, a relatively large deficit is necessary to raise the national income by a small amount. But a deficit may cause the investment function to shift to the left, especially if it arouses the expectation of higher taxes and if the government has manifested a strong propensity to tax profits. In this event, all or nearly all of the stimulus of the deficit may be canceled.[8] When

---

but more so in the second recovery than in the first. The following are the indexes of wholesale prices of raw materials and finished goods:

Year	Raw materials	Finished Goods
1921	88.3	103.3
1922	96.0	96.5
1923	98.5	99.2
1926	100.0	100.0
1933	56.5	70.5
1934	68.6	78.2
1935	77.1	82.2
1936	79.9	82.0
1937	84.8	87.2

A comparison of 1926 and 1937 is of interest. Output per man-hour in manufacturing in 1937 was apparently 33.2 per cent above 1926, hourly earnings 22.4 per cent above 1926. Finished goods were slightly higher relative to raw materials than in 1926. Nevertheless, non-financial corporations made profits of only 3.8 billion dollars on sales of 108.4 billion dollars in 1937, as against profits of 5.8 billion dollars on sales of 106.2 billion dollars in 1926—a margin of 3.54 cents per dollar of sales in 1937 and of 5.44 cents in 1926.

[8] Satisfactory information on the saving function is virtually impossible to obtain because the relation of consumption to income payments has been affected in recent years by changes in taxes and other conditions. These changes may or may not be permanent. Further changes appear to be ahead. At any rate, they indicate that attempts to deduce the saving function from time series are likely to have little significance for the future. Such information as is available indicates that in the range between a national income of 60 billion dollars and 80 billion dollars there is an increase of about 40 cents in saving for one dollar increase in income. Hence, a persistent deficit (or an increase in investment) of 4 billion dollars is necessary to raise the national income by about 10 billion dollars. If the persistence of the deficit were to produce an unfavorable shift in the investment function sufficient to cut private investment from 7 billion dollars to 5.25 billion dollars (or 25 per cent) at a national income of 70 billion dollars, almost half the benefit of the deficit would be lost. A shift of even greater magnitude in the investment function might easily be produced by expectations of higher taxes. During the last decade deficits have been working most of the time against a sharply declining marginal propensity to spend or invest additional income, as the drop in the velocity of bank deposits outside New York from 28.0 in 1933 to 22.6 in 1939 and 21.6 in 1940 plainly indicates. Of course, the drop in the marginal propensity to spend must be attributed to a variety of causes, but one of

neither rising national income nor rising tax rates reduced the deficit, who could avoid concluding that substantially higher taxes were ahead, and that, in view of the record, they might fall in substantial measure on profits?

To the influence of the deficit in producing an unfavorable shift in the investment function must be added tax changes well designed to discourage innovations and experimentation and to reduce the attractiveness of risky ventures. Between 1929 and 1936, the effective rate of the corporate income tax was virtually doubled.[9] It is no answer to say that the tax is eventually shifted, because it is passed on only by restricting the volume of investment. And since corporate profits are produced in a large measure by innovation and experimentation, doubling the tax on corporate profits amounted to doubling the tax on innovation and experimentation.

Some changes in tax laws were especially well designed to penalize chance-taking. The loss carry-over provision in the corporate income tax was limited to one year in 1932, abolished in 1933, and not restored until 1938. Capital losses, which had been fully deductible up to 1932, were deductible only to a very restricted degree throughout the entire critical period between 1932 and 1938.

Similar changes on an even more drastic scale were made in individual income tax rates. Until 1932, the highest surtax rate was 20 per cent, applicable on incomes over $100,000. In 1932 surtaxes were greatly raised. They were raised again in 1934 and 1936. Dividends from corporations were made subject to the normal tax in 1936. By 1938, the normal tax and surtax took 35 per cent of additional income immediately above $50,000; 51 per cent immediately above $74,000; and 62 per cent immediately above $100,000. How drastically tax increases reduced the marginal returns on investments in equities by the persons who did the most saving is illustrated by the fact that by 1938 a man with an income of $50,000 would need a yield of 8 per cent before his tax to obtain a return of 5.4 per cent. At the same time, the capital loss provisions of the income tax were modified to narrow greatly the opportunity to deduct capital losses.[10] In other words, the govern-

them seems to have been a conjunction of persistent deficits with a disposition to increase those taxes which must directly limit the marginal efficiency of capital.

[9] The base rate, which was 11 per cent in 1929, was raised to 12 per cent in 1930 and 13.75 per cent in 1932. The consolidated return was abolished for all corporations except railroads in 1934, intercorporate dividends were taxed in 1935, a tax on undistributed profits was added in 1936. Other changes which increased the effective burden, such as abolition of the loss carry-over and restriction on credits for capital losses, are discussed below. The corporate income tax was further increased by substantial additions to the base rates in 1938 and 1939, not to mention the subsequent increases required by the defense program.

[10] Up to 1932 capital losses could be deducted in full for periods up to two years. Above two years the taxpayer had the option of paying 12½ per cent as a tax or deducting 12½

ment was greatly increasing the difficulty of adding to one's capital by successful ventures and at the same time was severely limiting the possibility of charging unsuccessful ventures against successful ones. Can one imagine a better arrangement for encouraging investors to avoid venturesome commitments?

VI

What of the long-range outlook? If to shifts in economic and political power, which have already created difficult problems, is added a narrowed opportunity for extensive investment, does not the problem of providing employment become so formidable as to require great changes in policies and institutions?

One may assert with reasonable confidence, I think, that the consumption function will slowly become more favorable to employment. For more than a generation the propensity to consume has been rising just about fast enough to prevent the increase in per capita incomes from causing a drop in the proportion of the national income currently consumed. It is noteworthy, however, that in the twenties, despite the rapid rise in per capita income, capital formation was relatively less than in the preceding decade—19.6 per cent of gross product as against 22.8 per cent.[11] In the post-war world, the propensity to consume will be higher than in the twenties. Corporations will be hampered, as they have been for nearly a decade, in devoting part of their income to capital

per cent as a loss. The act of 1932 greatly restricted the deduction of short-term losses and the act of 1934 restricted the deductions of all capital losses to the amount of capital gains plus $2,000.

Mr. Alexander Sachs stresses the deterring effects in the act of 1938 of the disconnection between long-term and short-term gains and losses. If a long-term gain and a short-term loss are realized in the same year, the latter cannot be used to offset the former. Furthermore, if the short-term gain is not realized, the enterpriser is exposed to the danger that, in the event of the gain's becoming a loss, it can be credited only to the extent of 15 per cent or 20 per cent.

[11] S. S. Kuznets, "Capital Formation, 1879-1938," *University of Pennsylvania Bicentennial Conference*, p. 70.

The real rise in the individual propensity to consume was considerably more than is indicated by the figures of gross capital formation. The change in individual propensities to consume cannot be inferred entirely from the proportion of output devoted to capital formation. In the twenties a considerable increase in public capital formation (roads and bridges) was financed by new taxes such as gasoline taxes. Such capital formation, of course, represents no increased disposition on the part of individuals to save. It may be thought that the proportion of income devoted to consumption was abnormally high in the twenties because of the making of purchases postponed during the war and the liquidation of Liberty Bonds for that purpose. This may have been true for the first several years of the decade. But annual figures on capital formation indicate that the proportion of output devoted to capital formation tended to decline between 1923 and 1929, despite a rise in per capita real income.

Capital formation by corporations was facilitated by the fact that managements were not under pressure to restore previously high dividend rates and hence were fairly free to plow back a large proportion of increased earnings.

formation by pressure from stockholders to maintain dividend rates.[12] Post-war tax collections by the federal government will probably be at least twice pre-war. The additional amounts will be collected largely from the middle incomes.[13] Much of the saving of recent years has been temporary rather than permanent. This is true of the saving represented by premiums for life insurance, annuities, and pensions which in the main are intended to be consumed rather than to provide permanent sources of income. Benefit payments of life insurance companies are gradually catching up with their premium receipts and eventually the difference between the two will be little greater than the operating expenses of the companies.[14]

Too much importance, however, must not be attached to prospective changes in the consumption function. If there is a decline in the disposition to take risks in order to increase capital, and a rise in the desire to avoid risks in order to conserve capital, a drop in thriftiness may be accompanied by a rise in unemployment.[15] The large shift in the con-

[12] It is not generally known that throughout the recovery until 1939 dividend disbursements each year exceeded corporate earnings by a billion dollars or more.

[13] Satisfactory data are not available for estimating how much a higher tax burden would reduce savings in the middle incomes. One may roughly estimate, however, that in the case of incomes from $10,000 to $50,000 a year every additional dollar taken in taxes will reduce the volume of saving by 25 to 50 cents. The higher taxes will tend also to affect the slope of the function, making less pronounced the rise in the volume of savings which accompanies a rise in income. It might appear that this change, while making the economy more responsive to any stimulus, would also make it more unstable. This tendency will be largely offset, however, by the spread of unemployment insurance.

[14] Prior to 1929 the premiums of life insurance companies were increasing far faster than payments to policyholders. Between 1929 and 1940 the payments of life insurance companies to policyholders increased more than premium payments. Between 1929 and 1940 total premium income of life insurance companies increased from 3,350 million dollars to 3,944 million dollars, or 594 million dollars. Payments to policyholders increased from 1,962 million dollars to 2,681 million dollars, or 719 million dollars. (*The Spectator Life Insurance Yearbook*, 1935, pp. 414-15; and 1941, p. i.)

The disposition to save in years immediately after the war will be affected by the extent to which individuals and business enterprises reduce their debts during the war. Reduction of private indebtedness will assist in financing the war, provided creditors put the proceeds into government bonds. Reduction in mortgage indebtedness and installment debts should be encouraged both to finance the war and to create the basis for a high level of consumption in the years after the war.

A large rise in the price level during the war may have the net effect of raising the post-war propensity to save, because it will probably induce some attempts to restore the purchasing power of savings or of the income from savings.

[15] This is simply one way of saying that a favorable shift in the consumption function may be offset by an unfavorable shift in the schedule of liquidity preference. The desire for security of principal will be satisfied to a considerable extent by holding idle cash in the event that venture capital is not sufficiently abundant to provide a satisfactory cushion for new fixed income securities. There are several elements in thriftiness and they may change in relative importance. The kind of thriftiness that does most good is that which is based upon an attempt to increase one's capital.

It is possible, of course, to have steadily increasing unemployment because of an insufficiency of savings. The annual increments of investment-seeking funds may not be

sumption function in the United Kingdom between the pre-World War and the post-World War decades, as indicated by Colin Clark's estimates, did not prevent the persistence of a large amount of unemployment throughout the twenties.[16] Too much attention has been paid by recent economic theory to mere changes in the amount of thriftiness and too little to changes in the kind of thriftiness and to shifts in the propensity to invest.[17]

VII

The effect of the drop in the rate of population growth upon investment opportunity might seem to depend in the main upon how rapidly the marginal return on capital falls as capital per worker increases. Except for the investigations of Douglas, little work has been done on this point. The problem, of course, is not how marginal efficiency of investment behaves under static conditions but how it behaves under the rate and kind of technological change and the price movements that may be expected to occur. It is highly probable (though not inevitable) that technological change will increase the amount of capital that each worker can advantageously manage because inventions consist largely of making apparatus more automatic and adding automatic attachments. Douglas estimates that an increase of 270 per cent in fixed capital per worker in manufacturing between 1899 and 1922 was accompanied by a drop of 44 per cent in the marginal physical productivity of capital.[18] This is not a rapid drop and it occurred when technological research was on a far smaller scale than it is now. It is interesting to observe that the drop in the marginal physical productivity of capital was accompanied by a large rise in interest rates.[19] This contrast between the movement of interest rates and the marginal physical productivity of capital suggests in how great measure the marginal return

---

sufficient to provide plant and equipment necessary to enable the increment of workers to earn the prevailing scale of wages.

[16] Colin Clark, *National Income and Outlay*, p. 185.

[17] Liquidity preference appears to be sensitive to changes in investment opportunity. An improvement in the marginal efficiency of capital not only produces more investment under a given state of liquidity preference but also actually changes the state of liquidity preference; that is, produces a shift in the schedule of liquidity preference. Likewise, a drop in the marginal efficiency of capital produces a rise in liquidity preference. Furthermore, a rise in liquidity preference produces a drop in the marginal efficiency of capital and hence a further rise in liquidity preference. Because the marginal efficiency of capital and the schedule of liquidity preference are not independent variables, a change in either one of them is more important in determining the capacity of the economy to expand than changes in the consumption function.

[18] P. H. Douglas, *The Theory of Wages*, pp. 121, 125, 130, and 146.

[19] Macaulay's index of the adjusted yield of railroad bonds rose from 3.182 in 1900 to 5.168 in 1920. F. R. Macaulay, *The Movements of Interest Rates, Bond Yields and Stock Prices in the United States Since 1856*, pp. A 152, A 157.

on capital is determined by price trends and by expectations.[20] Of course, if the United States by any chance were able to arrange its affairs to permit the exportation of capital on a considerable scale in the post-war world, the problem of opportunities for extensive investment would be a generation or two in the future.

Technological research is growing rapidly, as the ninefold increase in personnel in twenty years indicates, and it will undoubtedly continue to grow rapidly. Indeed it must now be regarded as one of the most important instruments of economic adjustment. But even today there are only about 3,500 industrial research laboratories in the country. Out of over 100 billion dollars of sales by corporations only 300 million dollars goes into industrial research, or less than one-third of one per cent. Virtually half of all industrial research is done by four industries—chemicals, petroleum, electrical apparatus, and electrical communications. In 1940, there were about 15,000 chemists in industry and about the same number of engineers, but only 2,000 physicists.[21] Some people believe that the present war will put the physicists into industry in much the same way that World War I put the chemists into industry. Private enterprise has never yet had to face squarely the question of whether it is able to provide over the long term the amount of employment which the community expects. When it is confronted with this question, the expansion of industrial research may be considerable. Likewise one may expect considerable expansion of "new product" departments charged with the responsibility of discovering opportunities for new products and assisting in their development. Only a few concerns now possess such departments. Little has been attempted by public policy to make industrial research more easily available to small enterprises. All of this points to the conclusion that industrial research is in its infancy and that it offers a way of providing investment opportunities that will be far more important in the future than in the past.

VIII

By the end of the war, roughly one-third of the pay rolls of industry will be directly determined by collective bargaining. Wage rates in

[20] As men were thrown out of work in the capital goods industries through failure of the increase in the working force to create opportunities for extensive investment, the unemployed would become available for employment in new plants and on new machines and thus would furnish opportunities for extensive investment. But the idle plant produced by the contraction of employment would limit the return on new investment and thus tend to discourage it. Whether or not unemployment produced extensive investment, therefore, would depend upon the terms on which the unemployed would accept work. They would need to be willing to accept employment at sufficiently below current rates to make new investment opportunities attractive despite the existence of idle plant and machines.

[21] National Resources Planning Board, *Research—a National Resource*, vol. II, *Industrial Research*, pp. 176-77.

many nonunion plants will be sensitive to changes in union scales. The marginal efficiency of capital depends, among other things, upon the control of management over costs. In the face of large and powerful labor organizations, will American business possess sufficient control over costs to maintain a high marginal efficiency of capital? Or will unions keep investment opportunity limited by promptly converting any increase in demand for labor into higher wages?[22]

Many economists believe that bargained changes in costs are bound to be completely translated into higher prices, so that changes in the general wage level produce solely price effects and not output or employment effects. The relationship between bargained changes in costs and prices is undoubtedly the most important issue in the theory of employment. The conclusion that rises in costs are translated into higher prices so that the return on investments is not affected presupposes, among other things, a self-contained economy. But even in a self-contained economy, the assumed relationship between costs and prices requires a theory of liquidity preference which is not convincing. It is assumed that higher wages reduce liquidity preference and that the shift in the schedule of liquidity preference so increases the volume of active deposits that prices rise in proportion to the advance in wages. All of this amounts to assuming that the volume of deposits held idle is a residual and that it is independent of the purchasing power of the idle deposits.[23] These assumptions are far from realistic. If general increases in the wage level cannot be counted on to produce offsetting increases in expenditures and prices, a rise in labor's bargaining power will tend to reduce the marginal efficiency of capital.[24] The resulting

[22] In other words, will unions prevent any expansion of demand from producing more employment by causing it to produce higher wages?

[23] Suppose that the first reaction of managements to a rise in costs were to advance prices in proportion. To sustain the higher price level the public would have to be willing to hold a smaller amount of real purchasing power in cash. It is not clear why a rise in prices should produce this result, except as higher prices reduce the purchasing power of incomes. This might produce some tendency to reduce idle deposits. But the drop in the purchasing power of money would also limit the decrease in idle deposits since the quantity of money which people desire to hold idle is presumably affected by its purchasing power. Equilibrium would eventually be reached at some point below the original volume of output and employment, but with money expenditures somewhat above the original level. In the above analysis, it is assumed that the demand for assets in the form of idle deposits is such that idle deposits drop as the purchasing power of money drops. It is possible, however, that a drop in the purchasing power of money will cause an increase in the number of dollars held idle. In that event an effort to pass on an increase in costs in the form of higher prices would produce an even greater drop in output and employment.

[24] It is conceivable that wages might get so low and that such a large proportion of the national income might go to savings and such a small part to labor that further reductions in wages would cause more than a proportionate drop in total expenditures. As the increase in investment-seeking funds produced a drop in the marginal return on investments, the proportion of money held idle would increase. Eventually it would increase so rapidly as more than to offset the effect of the drop in costs and prices upon the physical

unfavorable shift in the investment function is not offset within the usual range of national income by the favorable effect of the redistribution upon the savings function.

The problem which confronts the individual investor or the enterprise is not the effect of general increases in wages on prices, but the effect of the spread of union organization upon the probable return from a particular investment. When one examines this matter, it is difficult to avoid the conclusion that large and powerful unions tend to reduce the marginal efficiency of capital. It is true that collective bargaining frequently raises plant efficiency by giving management better information about conditions and by giving representatives of the men an opportunity to point out mistakes of management. Nevertheless, powerful unions increase the likelihood that successful concerns will have to share their prosperity with the employees. Until recently there has been no offsetting protection against losses. The development of the policy of union-management coöperation during the last twenty years has interesting theoretical implications. Most of the coöperative plans have been started in high-cost plants. They have been a way by which the workers in these plants tried to safeguard their jobs. If union-management coöperation were to become widespread in high-cost plants, it would go far to offset reduction in the marginal efficiency of capital produced by the encroachment of unions on the profits of the most successful concerns. For the time being, however, one must conclude that the spread of unionization tends to reduce the marginal return of capital.

Are unions likely to reduce the return so seriously as to limit materially the capacity of the economy to expand? That is a possibility, but not a necessity, as the experience of the United Kingdom and Sweden shows. One may assert with confidence, I think, that even a large and powerful labor movement will be less harmful to expected returns on investments than the shift in power that has been going on since 1933.[25]

---

volume of transactions. Hence two zones might be distinguished: one in which expenditures change proportionately less than changes in wages and in which wage increases are unfavorable to employment; and one in which expenditures change proportionately more than changes in wages and in which wage increases are favorable to employment. In the former zone, the usual one, the effect of wage changes on the investment function would not be offset by their effect upon the savings function; in the latter zone, the effect of wage changes upon the investment function would be offset by their effect on the savings function. The latter zone would appear to be an unstable one because wage increases, by reducing unemployment, would produce more wage increases and because wage cuts, by producing more unemployment, would produce more wage cuts. As a matter of fact, wages in relation to prices apparently never get down into the zone of instability.

[25] Such a period of shifting creates great uncertainty over the future of costs. In the face of such uncertainty managers may be more reluctant to make long-term commitments than they would be after unions are better established and stronger, but when economic

There is nothing fixed or inevitable about the way in which collective bargaining operates and the effects which it produces. I have in mind a case where union policy has reduced output per man-hour over 40 per cent in seven years. I have in mind also a steel mill where the president recently said that he would not sell his plan of union-management coöperation for a million dollars. Such are the possible extremes. Management has it within its power to influence greatly the way in which collective bargaining operates. As managers become reconciled to the necessity of dealing with trade unions, they may be expected to be increasingly successful in gaining help on operating problems from unions. The effect of collective bargaining upon the marginal efficiency of capital will also depend upon the willingness of employers to organize. American employers have always been reluctant to organize for the purpose of dealing with labor. Most of their existing bargaining organizations are flimsy affairs with little discipline and meager resources. The success of collective bargaining in Sweden and the United Kingdom is largely attributable to the way in which the return on capital has been protected by large and powerful organizations of employers.

IX

The readiness with which an economy translates the results of technological progress into new investment, the resistance which it shows to depression, and the ease with which it recovers depend in large measure upon the willingness of individual enterprises to increase their expenditures for equipment and for the development of new products more or less regardless of the general business situation—to step out in advance of other concerns and make commitments. In other words, it depends upon the relative attractiveness of venturesome and daring production plans in comparison with cautious production plans. The dynamic influence of venturesome production plans has been underrated in recent economic analysis, largely because the contagious effect of investment by one firm in compelling offsetting investments by rivals has received little attention.

The government, through the way in which it raises its money, has wide discretion in determining the relative attractiveness of different types of production plans. This is especially true when the government

power is no longer shifting. It is to be observed also that the large wage increases between 1936 and 1937, when the hourly earnings of factory workers increased by 12 per cent, were not in the main directly produced by trade unions. In large measure they represented an unsuccessful effort on the part of employers to stop the spread of labor unions. As a matter of fact, the wage increases seem to have stimulated the growth of unions by convincing the men that there was a lot of easy money around which they might get by organizing. Some employers who gave a wage increase to prevent their men from organizing had to give a second increase after the men had formed a union.

takes such a large proportion of individual and corporate incomes as it now does. Taxes in recent years have been remarkably well designed to bear heavily on any enterprise which displays daring, which backs an innovation or an experiment, especially an experiment which is pretty certain to experience losses for several years. The loss carry-over provisions of the corporate income tax could be modified, for example, to facilitate substantially the accumulation of capital by new concerns. In times of poor economic visibility and rapid technological change, much is to be said for a flexible treatment of depreciation allowances. Enterprises should be encouraged to write off half of the cost of new assets during the first three or four years of their life. This would increase the subsequent tax liability of the concern, but it would make uncertain ventures less risky. A large reduction in the tax on that part of corporate profits spent for plant and equipment (the reverse of the undistributed profits tax) would help restore the practice of plowing back earnings—so important if new concerns are to furnish stiff competition for old ones and important in the case of all concerns in stimulating the kind of investment which starts expansion and improves the ability of the enterprise to attract funds from the outside. A similar principle might be applied to the personal income tax. In the case of this tax there is conflict between the community's interest in the principle of ability to pay and its interest in expansion. Stiff surtaxes greatly reduce the marginal efficiency of any investments made by large income recipients. These surtaxes are in conflict with prevailing theories of liquidity preference. It would not be necessary to repeal the surtaxes. The attractiveness of uncertain ventures to large income recipients (or even persons in the middle brackets), could be increased by a substantial reduction in the surtax on that part of income invested in non-refunding equities.[26]

X

The ability of the community to supply itself with enterprise will depend also upon the organization of the capital market. At the present time this is in a state of flux, partly because of recent legislation and partly because changes in the tax system require that machinery be developed for obtaining venture capital from income brackets which have provided little of it. It is important to realize that neither the volume of investment opportunities nor the volume of investment-seeking funds is fixed. Each is the result of discovery and of effort. It

[26] The effect of the tax upon production plans depends in substantial measure upon whether enterprises are discounting increases or decreases in taxes. Post-war adjustments will be greatly assisted if enterprises are discounting decreases in taxes. Certainly the prospect of tax reductions was an important stimulus to business during the five years following the First World War. If one may assume post-war federal budgets not in excess of 14 to 15 billion dollars a year, the prospect of reduction in taxes would be good.

takes work and money to find good credit risks which could use funds and to find people who might be persuaded to buy particular types of securities. Many men make their living by doing these things. How dynamic the economy is able to become will depend partly upon how good a job is done in adapting the machinery of the capital market to new conditions.

XI

To a very substantial extent, of course, the opportunities for investment will be affected by the policies which the United States elects to pursue toward the rest of the world after the war. If conditions are reasonably stable, opportunities will exist for large international movements of capital and for extensive investment on a broad scale. Indeed, the potentialities of this are enormous. Here we see perhaps more plainly than ever how dependent investment opportunity is upon policy, for the problem of providing the basis for large international capital movements which will greatly raise the standard of living of the entire world is, in the main, a political one.

XII

One may infer from this survey that the outlook for employment during the post-war generation is not necessarily dark. In fact, it may turn out to be distinctly good, especially in the event, by no means improbable, that the country is able to create favorable conditions for large capital exports.[27] But my purpose in this analysis has not been to speculate about the future, because anything can happen. Rather my purpose has been to focus your attention upon certain characteristics of our economy. The conclusion to which I invite your attention is that most of the variables which determine the amount of private employment and the rate of expansion are influenced within wide range by policies, public and private. This is true of the relation between costs and prices; of the way in which cost curves shift in response to changes in demand; of the quantity of resources, public and private, devoted to technological discovery; of the disposition to venture, and the relative preference for various types of production plans; of the position and income elasticity of the savings function. No fixed or inevitable values may be assumed for these determinants of expansion. Hence

[27] Should the defeat of Germany mean domination of Europe by Russia, the economic future of the United States will be determined in great measure by Russian economic and political policy. If American business men are sufficiently ingenious to develop a large market here for Russian goods and if Russia does not revive her policy of world revolution, the possibilities of a large and mutually advantageous exchange of goods between Russia and the United States are bright. The pre-war experience of Germany, the United Kingdom, and the United States indicates that trade need not be in the main between industrial and agricultural countries.

there is no fixed amount of investment opportunity, no fixed willingness to take chances, no fixed demand for goods or for people to make goods. All depend upon conditions, and all may be greatly influenced by policy.

Some of the policies which determine the volume of employment represent a deliberate choice between employment and something else. There may be a clash, for example, between the interest of the community in full employment and its preference concerning the distribution of wealth. Since tax changes which would raise the marginal return on investments by the well-to-do would facilitate the acquisition of large fortunes, the community may accept a limited amount of private employment in order to achieve a more even distribution of wealth.[28] The policies which represent a deliberate and informed choice between employment and something else are not our problem. Many of the policies which affect employment, however, are not intended to do so. The groups which produce the policies are too small to consider their consequences for employment and yet the total effect of the policies of thousands of organizations of business men and farmers, thousands of local unions, and many states, counties, and cities upon cost-price relationships and upon the opportunity to experiment and to introduce innovations is considerable.

Because many policies are pursued without regard to their effect upon the general level of employment, the persistence of unemployment cannot be counted upon to produce the changes in policies which are needed to increase employment. If the bargaining power of labor, for example, is too great in relation to the rate of technological discovery so that the investment function does not permit a satisfactory level of employment, there is no automatic change in policies to reduce the bargaining power of labor, to raise the rate of discovery, or to produce a shift in the propensity to save. These things *may* happen, but they cannot be counted upon to happen. In fact, the response of policies to unemployment may in the main be bad: unemployment may provoke a flood of attempts to protect markets by restrictions which narrow the area of innovation, cut the marginal return on investments, and produce unfavorable shifts in the schedule of liquidity preference. Numerous examples of this kind of response to unemployment can be gathered from the recent depression both in the United States and abroad.[29]

[28] One of the broadest conflicts in the community is the competition between the old and the new. Much intervention on behalf of the government is simply a way of protecting the old from the competition of the new. Of course, the farther the government goes in protecting the old from the new, the more it limits investment opportunity and, to that extent, employment. But most of the community may prefer less private employment to a faster rate of change.

[29] The most conspicuous illustrations can be drawn from the field of international economic policy, but many others could be cited.

If the level of employment is unsatisfactory from the standpoint of the community, who is to assume responsibility for seeing that policies are modified or broadened so as to permit the largest amount of employment compatible with the other interests of the community? To some extent the government can assume this responsibility. The government has three principal ways of affecting the general level of employment: (1) the method of correction, (2) the method of compensation, and (3) the method of stimulation.

The method of correction involves making changes in public policies or forcing changes in private policies in order to increase employment or, put in other words, altering the distribution of economic advantages in order to increase the total amount of income.[30] Many public policies—tax policies, regulation of security markets, price-pegging schemes—were adopted without an appraisal of their probable effect upon employment and even without a suspicion that there was a problem of maintaining employment. Recognition of the existence of such a problem may lead the community to prefer to revise many of its policies. The policy of correction would also involve the assertion of some public control over private policies. There are various ways by which the government might exercise such control, but on the whole the possibilities are limited because, in many cases, control cannot be accomplished without a large number of detailed regulations which would be impracticable to administer.

The method of compensation involves an attempt by deficit financing to offset the failure of private enterprise to provide a satisfactory amount of employment; note that I do not say "full employment." Strictly speaking, the method of compensation should not be used until the community has gone as far as it is willing to go in applying the policy of correction. Otherwise, the policy may divert the government from thoroughly exploring the possibility of enforcing changes in private policies that would raise the level of employment. In fact, the persistent use of the policy of compensation may stimulate a development of private policies that are unfavorable to employment. Why should an up-and-coming labor movement, for example, permit the demand created by public spending to produce more employment rather than higher wages?

The use of deficits to compensate for a chronic shortage of investment opportunities raises very different economic issues from those involved in the use of deficits in periods of depression when there are

[30] One might visualize as an ideal a central planning agency charged with the responsibility of reviewing the obstacles limiting the amount of enterprise and of estimating how much sacrifice by different groups would produce how much expansion in employment. These reports might be referred to representative agencies to determine which interests to sacrifice for the enlargement of income.

idle resources of all sorts. Although the tax expectations aroused by a persistent use of deficits do not necessarily reduce the marginal efficiency of capital, as a practical matter it is very difficult to prevent this effect. There are also likely to be important differences in the economic effects of public and private investment which prevent the former from being merely an offset to the latter. Private investment, being intended to yield a profit, represents an attempt to anticipate trends in consumer demand and thus to keep the pattern of productive capacity adjusted to the pattern of consumer demand.[31] To the extent that this happens, private investment tends to produce a rise in output and employment rather than in prices. Public investment, on the other hand, does not as a rule represent an attempt to adjust productive capacity to consumer demand. Hence, if public spending occurs on a large scale after plant is fairly well employed, its effect will be in the main to raise prices rather than to increase employment. Consequently, the policy of compensation seems to have a much narrower application than most of its proponents have assumed.

The method of stimulation involves expenditures by the government which are designed to produce favorable shifts in the private investment function. Expenditures on roads or air ports and, in some instances at least, on rivers and harbors are an example, but the outlay in fact may take a wide variety of forms. The support of agricultural or industrial research is an example. Note that the efficacy of the method of stimulation does not depend upon the expenditure's being financed by borrowing. The essence of the method is that a public expenditure (or loan) is creating a private investment opportunity which would not otherwise exist. The method is not a new one, but it is susceptible of considerable expansion.

XIII

This brief review of the possibilities of public policy leads one to the conclusion that the range within which the government can influence the level of employment is broad but, nevertheless, in a non-regimented economy, limited. Given a fairly rapid rate of technological change, a fairly even balance of power between employers and workers, and a well-organized capital market, the community with the help of the government may maintain a satisfactory level of employment. But we cannot be sure. This brings us to the final and most basic consideration. Both what the government needs to do and what the voters will permit the government to do depend in the last analysis upon the valuations

[31] How imperfectly even private investment accomplishes this result is indicated by the jerkiness with which growth occurs. Partly because the pattern of productive capacity does not accurately fit the pattern of consumer demand (and partly because of the nature of costs), the economy during periods of expansion usually presents a mixture of unemployment and inflation.

which individuals place upon group interests and common interests.[32] There are two ways in which groups may advance their interests. One is based upon a high valuation of one's special interests, and involves improving the bargaining position of the group for the purpose of getting a larger share of an income flow with little regard to the effect upon the size of the total income flow. The other is based upon a high valuation of general interests and involves restraint in pressing special claims which conflict with general interests.

It is not for the economist *qua* economist to quarrel with the valuations which individuals and groups place upon their interests. He is, however, within his scientific rights when he points out that these valuations have profound economic effects. They determine both the methods of production which it is possible to use and the quantity of goods that can be produced. High valuations of special interests can throttle production and render the government and every one else incapable of providing a satisfactory level of employment. High valuations of common interests will produce public and private policies that will prevent there being a problem of long-term unemployment.

Is it at all thinkable that groups of workers, employers, and farmers in dealing with one another and in pressing claims for legislation will be limited or guided to a substantial extent by concern for the national income? Or as these groups become more and more highly organized and more and more conscious of their particular interests, will they become less and less disposed to place high valuations on common interests? No one knows. Larger units of decision would help. Wage policy, for example, which is now made by groups too small to feel much responsibility for the general level of employment, might be made by units such as the United States Chamber of Commerce and the National Association of Manufacturers on the one hand and the American Federation of Labor and the Congress of Industrial Organizations on the other.[33] Perhaps new machinery must be invented in order that all groups may agree on the restraints that shall be placed upon their special interests and in order to make possible new ways of promoting common interests.

A lively concern for common interests by well-organized and self-conscious special groups may seem a utopian dream; but in an economy in which the policies of government and of large private groups determine employment, what substitute is there for it? The possibilities of

[32] It is not intended to deny that the valuations of the individual member of a group are molded largely by the leaders of the group. Consequently, the kind of valuations of group and common interests which emerge are determined in large measure by the kind of men who lead groups.

[33] In Sweden the recent depression produced rudimentary beginnings of a national wage policy made by the federation of employers and the federation of unions. See P. H. Norgren, *The Swedish Collective Bargaining System*, p. 303.

modern technology are tremendous. If these possibilities can be realized, no one can doubt that we are on the threshold of gaining a far better standard of living than man has ever known. Nothing can prevent us from realizing the possibilities of modern technology except unwillingness to place a high valuation upon certain common interests—particularly our interests in enterprise, experimentation, innovation. Never have the rewards of a broad view of common interests been more attractive. Never has the folly of narrowly pressing special claims been greater. The economic future of our country and of the world depends upon the clarity with which this is seen.

STATISTICAL INVESTIGATIONS OF SAVING, CONSUMPTION, AND INVESTMENT[1]

By MORDECAI EZEKIEL

I. SAVING, CONSUMPTION, AND NATIONAL INCOME

This study deals with the functional relations between national income, consumption, saving, and private investment, as indicated by statistical analyses of their behavior in the United States over the past two decades.[2] This paper considers income, saving, and consumption relations. A second paper will present the income and investment relations, and will compare them with the results shown here.[3]

The major magnitudes which are involved in this analysis are illustrated diagrammatically in Figure 1. Column I of this diagram represents the income received by producers of goods and services, after deducting costs of the raw materials consumed by producing units. The upper portion represents consumers' goods and services, the lower

[1] This report covers one of a series of studies under way during the past several years on the general interrelations of agriculture and industry. These studies have led to the conclusion that many farm problems, such as restricted domestic markets, excess farm population, and technological displacement, could find lasting solution only in reasonably full industrial production and employment. This has led in turn to reconnaissance studies in the field of industrial economics to determine basic reasons for chronic industrial unemployment and low production and to develop possible programs of action to correct those situations. The author feels that perhaps three-quarters of the farm problem lies in this field of industrial economic policy, and that programs or actions of farmers themselves can do little to correct this phase of the farm problem. Hence this exploratory work.

[2] I am indebted to John Maynard Keynes, Alvin Hansen, Gerhard Colm, Walter Salant, Hans Neisser, and A. Smithies, who read the study in manuscript and made many valuable suggestions. Credit is also due to Virginia D. Reeve for carrying through the compilation and statistical analyses of the materials for this study; for bringing together and abstracting the bibliographical material; and for preparing the first draft of the portion of the study dealing with the consumption function.

[3] Previous studies of the relations of saving, consumption, investment, and income have been less inclusive than the present study, though many of them have covered data from other countries as well as the United States. See J. M. Keynes, *The General Theory of Employment, Interest, and Money* (New York, Harcourt Brace, 1935), pp. 101-04, 127-28; R. and W. M. Stone, "The Marginal Propensity to Consume and the Multiplier, a Statistical Investigation," *Rev. of Econ. Studies,* Oct., 1938; Elizabeth W. Gilboy, "The Propensity to Consume," *Quart. Jour. of Econ.,* Nov., 1938; J. J. Polak, "Fluctuations in United States Consumption, 1919-1932," *Rev. of Econ. Stat.,* Feb., 1939; J. Tinbergen, *Statistical Testing of Business Cycle Theories;* Part II, *Business Cycles in the United States of America, 1919-32* (Geneva, League of Nations, Econ. Intelligence Serv., 1939); and Alvin Hansen, *Fiscal Policy and Business Cycles* (New York, Norton, 1941), chap. 11, pp. 225-50, with appendix by P. A. Samuelson.

portion, producers' goods and services. Both include goods and services produced by public agencies. The portion of producers' goods and services above the zero line represents net capital formation. The portion below the line represents producers' goods used for the replacement of worn-out or obsolete equipment.

Column II represents all expenditures by final purchasers of goods and services, divided into expenditures for consumption and expenditures for capital formation and maintenance. Since the amounts spent for final goods and services by the buyers must exactly equal the amounts received from the sale of final goods and services by the seller,

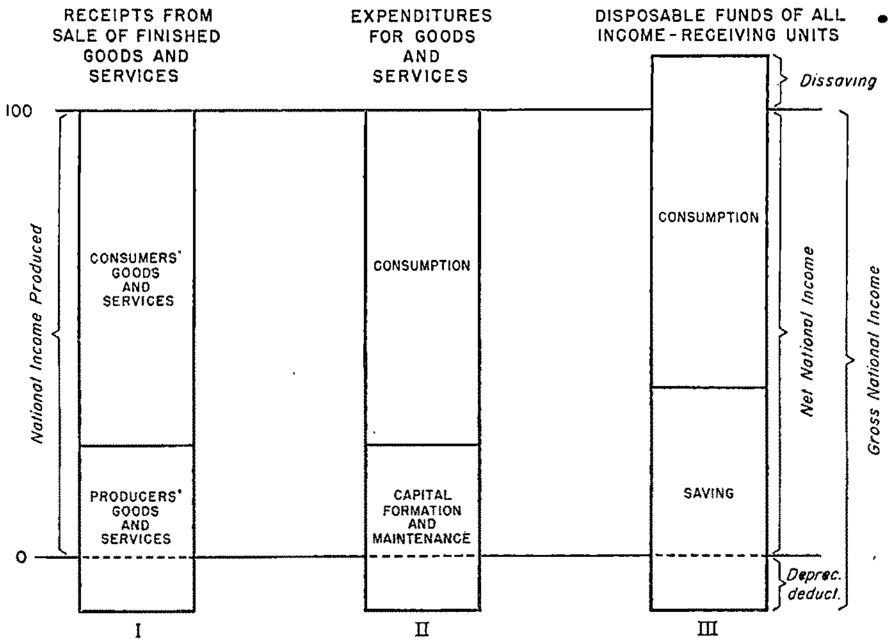

Fig. 1—Concurrent Relations of Income, Consumption, Saving, and Investment.

the two sections of Column II are the same as the two sections of Column I.

Column III represents the disposable funds received by all income-receiving units—business, personal, and governmental. The amounts set aside as deductions for depreciation and obsolescence are represented by the portion of the bar below the zero line. The upper section of Column III represents the net income used for consumption; the lower portion down to the zero line, represents the net income set aside as saving. Gross saving available for investment includes both this net saving (above the zero line) and the depreciation and depletion deductions (below the zero line). The net saving section of Column

III includes both private saving and business saving recognized as such. If businesses make further real savings by actually spending on replacement of depreciation and obsolescence less than is set aside as reserves for that purpose, then a portion of the section below the zero line is added to the funds available for new investment.

Figure 1 is drawn to illustrate the situation when gross saving exceeds the amounts actually spent for capital formation and maintenance, including capital formation financed by public expenditures. This difference will hereafter be referred to as the "gap." As shown in the figure, funds available for consumption (the upper portion of Column III) are just as large as expenditures for consumption (the upper portion of Column II). This is made possible only by adding dissavings to the disposable funds. These dissavings include government expenditures in excess of government receipts other than for capital formation, increases in consumers' credit and other borrowing of new funds or drawing down of old savings for consumption. Dissaving is represented by the portion of Column III above the 100 line. The amount of the dissaving is precisely equal to the gap between gross saving and gross capital formation and maintenance. If for any reason the amounts added to disposable income fail to equal the gap, then expenditures for goods and services will decline, fewer goods and services will be produced and sold, national income will fall, and net income received by individuals and concerns will decline. It is only when the amounts added to disposable funds precisely equal the gap that production and income can be maintained at the levels indicated.[4]

Basic Hypotheses

It is desirable to state as clearly as possible the hypotheses which it is proposed to test, and the way in which the data are to be organized as a basis for those tests. The hypotheses are:

1. Saving is a function of the current level of income, increasing as the level of income increases, but at a higher rate.

2. Consumption is a function of the current level of net income, increasing as the level of income increases, but at a lower rate than income.

3. The patterns of thrift, expenditure, and consumption at any given level of income are habitual patterns of action, changing only gradually in time, so that changes in current income received by each group produce reasonably consistent changes in total consumption and saving.

[4] This is obviously an oversimplified statement of the saving-investment balance as developed by Keynes and others.

Statistical Measures Employed

The statistical measure used for the level of income is generally the estimate of gross national income, without correction for changes in price level. For many elements in income and expenditure, dollars are a more unvarying measure than is "real production."[5] Where consumption is related to income, the net national income is used since credits to depreciation and depletion reserves presumably will not affect consumer expenditures. Direct annual data on saving of satisfactory accuracy are not available. The Brookings studies[6] and Dr. Kneeland's estimates based on the national survey of consumers' expenditures[7] have provided estimates of private saving for two given periods, 1929 and 1935-36. In the upper income brackets these estimates are based on very fragmentary reports. Other studies have extended these estimates over longer periods, on the assumption that the proportion saved at each income level was a constant.[8] The use of that assumption makes it impossible to test its accuracy from the resulting estimates. Changes in the comparability of income-tax reports and lack of adequate current information on the distribution of incomes below the income tax levels further reduce the value of these annual estimates. Another approach has been to build up a synthetic estimate of saving from reports of insurance companies, savings banks and other institutions receiving savings, plus estimates of direct investment by the saver.[9]

Other estimates of saving have been based on the uses made of saving, as recorded in various expenditures which use up or offset current saving.[10] That is the method used in the preparation of the savings series employed in this study, as given in detail subsequently. In effect, this method estimates the volume of saving (as shown in Column III of Figure 1) by calculating the volume of capital formation and maintenance (shown in Column II) and adding to it the volume of dissaving (at the top of Column III).

[5] As is indicated subsequently, tests were also run in some of the analyses using deflated figures.

These various measures of saving yield estimates which vary not only in absolute amounts, but also sometimes in direction of movement from year to year. In view of this weakness of the basic data, the conclusions must be regarded as showing general relations rather than precise measurements of facts.

The data used in the independent study of consumption are the latest estimates by Kuznets.[11] They are built up to some extent independently of the series measuring saving.

The Data on Saving

The most recent estimates of total saving, as shown by the offsets to saving series, are shown annually in Table I and quarterly in Table II.[12] The component elements of these data are as follows:

1. Expenditures for new durable producers' goods including plant and equipment. These data are built up from separate estimates for many individual industries.[13] (Various minor revisions made subsequently in the over-all figures have not as yet been carried back to these separate estimates.)

2. Expenditures for the increase (or receipts from the decrease) of the quantity of products in inventories.

3. Expenditures for new housing and other non-industrial construction.

4. Expenditures by consumers for other durable consumers' goods in excess of purchases paid for from current incomes. This definition excludes from saving expenditures for consumers' durables covered from current budgets or liquid funds of consumers, and includes only that part which is financed through net additions to consumers' credits. In periods when repayments exceed new borrowings, this results in a negative figure.

5. The net balance of buying power from foreign debits, for exports and intangibles, in excess of corresponding foreign credits, excluding gold and specie movements. These net foreign balances measure the extent to which incomes in this country were maintained by our

[11] Simon Kuznets, *National Income, 1919-38*, Occasional Paper No. 2, Nat. Bur. of Econ. Res., Apr., 1941.

[12] The annual data were first developed by Dr. Lauchlin Currie, formerly of the Federal Reserve Board, and were presented to the Temporary National Economic Committee on May 16, 1939 (*loc. cit.*). They are based in part upon estimates of new durable goods purchased annually for U.S. consumption calculated by George Terborgh, Federal Reserve Board. The data presented here are revisions of that earlier data. The monthly series from which the quarterly series is derived was developed subsequently by V. Lewis Bassie in the Division of Industrial Economics, Department of Commerce, under the direction of Dr. R. V. Gilbert. Acknowledgment is due these gentlemen and these agencies for permission to use these data.

TABLE I—GROSS NATIONAL INCOME AND INCOME-PRODUCING EXPENDITURES THAT OFFSET SAVING, BY YEARS, 1921–40
(in millions of dollars)

Year	Gross National Income	Income-producing expenditures that offset saving							
		Total	Equipment	Plant	Housing	Consumers' Credit	Net Foreign Balance	Inventories	Government Net Contribution
1921	63,751	9,548	2,758	2,475	2,313	−20[a]	1,327	47	648
1922	64,295	11,870	3,140	2,644	3,801	730[a]	293	514	748
1923	74,784	16,990	4,622	3,280	4,821	1,046[a]	−91	2,964	348
1924	75,161	13,279	4,343	3,307	5,229	311	530	−1,056	615
1925	79,686	17,032	4,598	3,591	5,750	842	199	1,523	529
1926	84,813	16,760	4,941	4,185	5,535	648	−39	1,246	244
1927	82,708	15,328	4,644	4,133	5,357	217	301	308	368
1928	86,167	16,039	4,743	4,103	5,019	821	518	102	733
1929	89,984	17,280	5,590	4,559	3,764	987	446	2,713	−709
1930	79,764	9,709	4,568	3,769	2,292	−613	632	−1,190	251
1931	63,901	5,360	2,940	2,182	1,734	−1,128	162	−2,278	1,748
1932	47,446	2,025	1,606	1,197	713	−1,485	132	−2,018	1,880
1933	46,217	3,225	1,503	866	461	−140	205	−1,598	1,928
1934	55,839	8,530	2,306	1,131	521	415	459	270	3,428
1935	61,681	10,312	3,092	1,260	918	858	181	273	3,730
1936	71,400[a]	14,281	4,134	1,651	1,536	1,355	−179	1,447	4,337
1937	79,400[a]	14,211	5,280	2,294	1,910	891	−5	2,749	1,092
1938	70,800[a]	8,457	3,618	1,776	1,817	−1,400	1,030	−758	2,374
1939	75,710[a]	15,165	4,289	1,852	2,270	907	781	1,415	3,651
1940	82,000[a]	17,580	5,751	2,360	2,431	1,014	1,417	733	3,874

[a] Estimated.

Note: For sources and methods, see statement submitted to the Temporary National Economic Committee by Lauchlin Currie on May 16, 1939 (*loc. cit.*). See also, Oscar L. Altman, *op. cit.*, Table 2, p. 14; and page 26, footnote 12 of this text.

receiving more from sales abroad than we paid back for purchases from abroad. These excess foreign payments, in the form of gold movements, of net credit extensions by us, or otherwise, provide a market for domestically-produced goods the same as if they were purchases of consumers' or durable goods by domestic purchasers.

6. The final item in the offsets to saving series is the government net contribution. This represents in general the excess of those public expenditures (federal, state, and local) that add to disposable private income over those tax receipts of the type that reduce disposable private income. These expenditures have been designated "income-increasing disbursements" and include:

a. Direct payments of income to individuals.
b. Purchases of materials and supplies.

c. Outlays on public works other than those made in the form of direct payments of income.
d. Loans to enable others to carry out new activities which result in the payment of income.

Thus gross public expenditures are adjusted to eliminate certain items designated as "non-income-increasing disbursements," such as refinancing mortgages or retiring public debt, since these are not likely to result in additions to consumption expenditures by the recipient. Government receipts have also been adjusted to eliminate estate and gift taxes, since such taxes are not likely to lower the level of consumption of the taxpayer.[14]

The sum of all these items, representing all income-producing expenditures other than for consumers' goods purchased from current incomes, is taken as the measure of saving and of investment. Actually, these items include two which do not constitute investment in the ordinary sense of the term.

The data on saving differ slightly from the simplified presentation of Figure 1. That diagram included under capital formation that portion of government construction which is financed out of deficit expenditures, and included under dissaving only the portion of the "net government contribution" which goes for consumer goods. The statistical data modify the arrangement slightly by including all expenditures from the net government contribution under dissaving. This would involve changing Figure 1 to split the lower section of Column II into two sections, one at the bottom representing "usual capital formation and maintenance," and a section above it representing "capital formation and maintenance covered by government deficits." The gap would then be the difference between saving and the lower (usual) section of capital formation and maintenance. Increases in the volume of consumer credit, and public borrowing for other than construction purposes, represent dissaving by the borrowing individual or government unit, and are thus offsets to saving by others.

The measure of saving used accepts the Keynesian definition that over any given income period saving and investment must be equal. The important question, however, is not whether saving equals investment in this accounting sense, but at what level of income and employment the two are equal. The way in which saving is at all times kept equal to investment determines whether income is rising, falling, or maintaining the same level. For example, if the individuals in the nation decide to save a certain portion of their expected income, but

[14] Martin Krost, *The Measurement of the Net Contribution of the Federal Government to National Buying Power* (Washington, Federal Reserve Board, Aug. 16, 1938, mimeo. pub.).

not all of the portion which they plan to save gets used somewhere to purchase goods and services, the level of income will fall. Since the total income of the nation in a given period is just large enough to take the current output off the market, and some of the intended output will not be salable at the existing prices, business enterprises will suffer losses and payrolls will be reduced. Contraction continues until the nation as a whole is forced to reduce its saving to an amount that can currently find investment outlets. Conversely, if the individuals of the nation plan to make new investments in excess of the amounts which as a whole they plan to save, expansion takes place. The injection of purchasing power through the creation of bank credit or in other ways causes demands to rise. Business enterprises increase operation, and production and incomes rise until the increased income of the nation as a whole can provide the extra saving needed for the new investment.

The annual amounts of saving, measured by the offsets, correspond fairly closely with the annual amounts of gross capital formation. This is evident when the two are charted together, as shown in Figure 2. Gross capital formation includes expenditures for public construction, while the saving figure includes instead the net contribution of government (explained above, page 28). The two series also differ in other respects.[15]

The Functional Relation of Saving and National Income

We can now proceed to test hypothesis 1, that saving is a function of national income. The simplest approach to this relation is presented in Figure 3. Here quarterly totals of the monthly data on saving are plotted on a time chart, in comparison with the quarterly totals of national income.[16] The data for this figure (Table II) are available only since 1929. The close correspondence between the two series is at once evident. The two rise and fall together, and the turning points are fairly close.

At the low points—1932-33 and 1938—saving reached its low while income was still declining, and turned up again as soon as the *rate of decline* in income began to slacken off. At the high, in 1929, saving also turned downward somewhat ahead of income, with the rate of

[15] The data shown in this figure are taken from Altman's monograph, *op. cit.*, pp. 13-14. See also Appendices XVII and XVIII, pp. 125-26, for a detailed breakdown of the two series.

[16] The quarterly totals of national income are derived from the Monthly Income Payments series of the Department of Commerce plus an adjustment for business savings. Data for national income produced or for gross national product are not available on a monthly basis. Since revisions in the Department of Commerce series are being undertaken, and since the estimates for quarterly business savings are necessarily rough, these totals are only rough approximations.

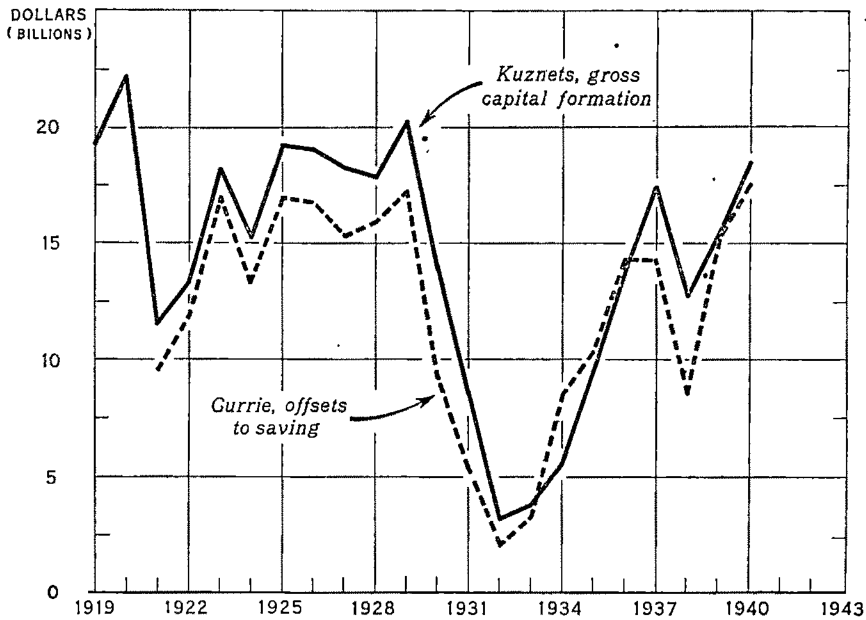

FIG. 2—Estimates of Gross Saving, 1919-40.

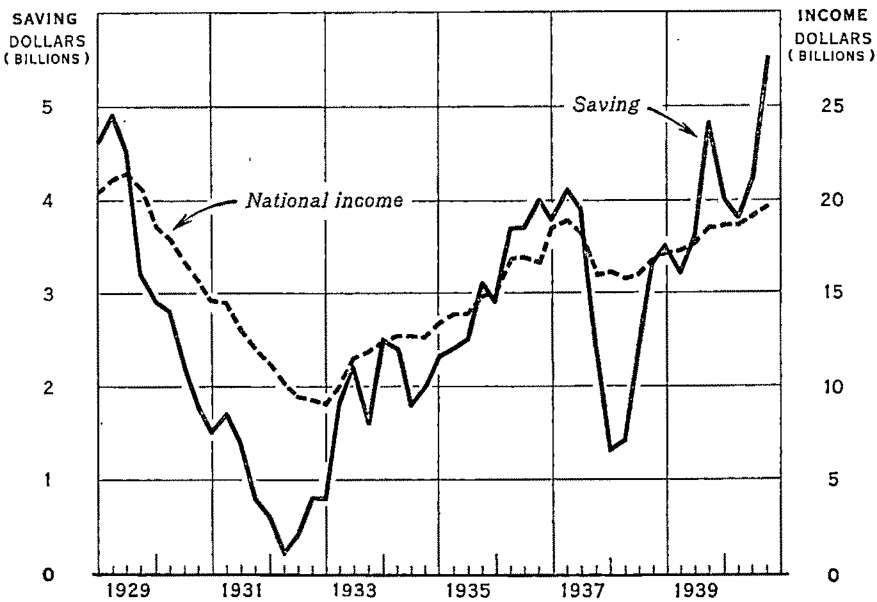

FIG. 3—Saving and National Income, 1929-40 (adjusted for seasonal variation).

decline in saving greatly accelerated as soon as income began to fall. Annual data for saving are available back to 1921. The relation of changes in saving to income from these annual data are shown in Figure 4. Here the gross national income is used.[17] Over the two decades

TABLE II—TOTAL OFFSETS TO SAVING AND NET NATIONAL INCOME, BY QUARTERS, 1929–40
(adjusted for seasonal variation)
(in billions of dollars)

Year and Quarter		Offsets to Saving[a]	Net National Income[b]	Year and Quarter		Offsets to Saving[a]	Net National Income[b]
1929	1	4.6	20.4	1935	1	2.3	13.3
	2	4.9	21.1		2	2.4	13.8
	3	4.5	21.4		3	2.5	13.8

[b] For source see page 29, footnote 16.

shown, saving and income fluctuate closely together. The peculiar lag in the relation which appeared in Figure 3 is less evident in Figure 4, apparently being concealed in the annual averages except in 1932-33.

The general relations shown in Figures 3 and 4 can be reduced to a more definite functional relation by correlating saving with income. Using annual data to simplify the presentation, the general functional

[17] The gross national income equals the net national income plus business deductions for depreciation and depletion. For derivation of this series, see Altman, *op. cit.*, p. 14.

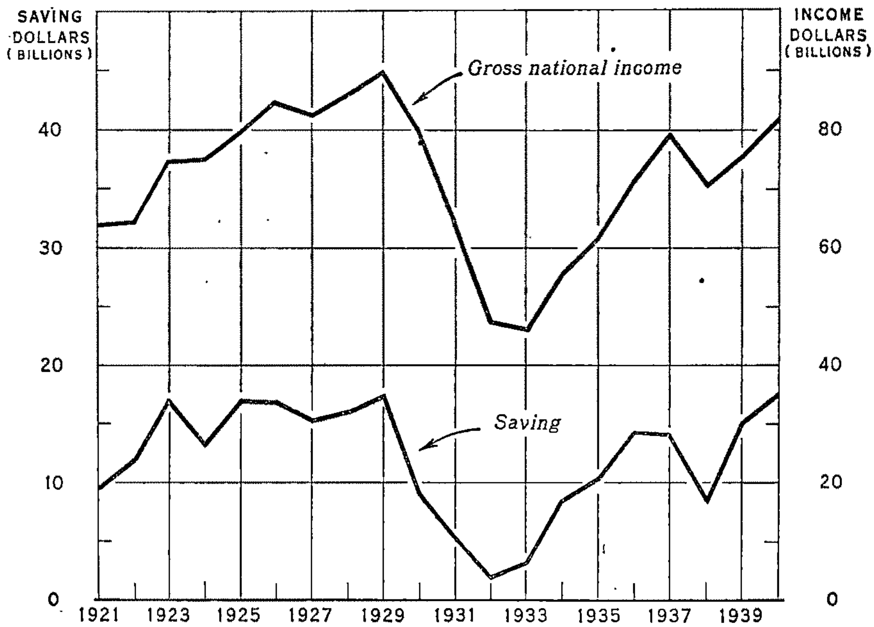

FIG. 4—Saving and Gross National Income, 1921-40.

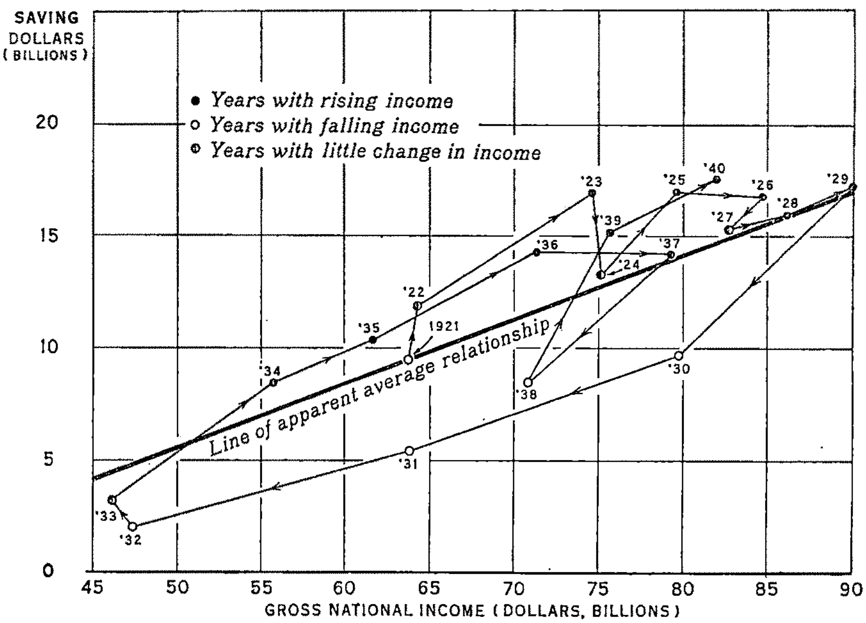

FIG. 5—Correlation of Saving and Gross National Income, 1921-40.

relation is shown in Figure 5. Here the dollar amount of saving is plotted against the dollar amount of gross national income, with a single dot representing each year. Successive years are connected by a light line, to indicate a trend if one is present, with arrows indicating the direction of the line in time.

Superficial examination of the chart indicates a marked functional relation between income and saving, with the saving for any given income falling generally within a zone of not wider than 8 billion dollars. There is no definite sign of a long-time secular trend, since the level of the data for 1934 to 1940 coincides almost exactly with the comparable level for 1921 to 1926. A continuous heavy line has been drawn in to indicate the apparent average saving corresponding to a given income. Closer examination of Figure 5 reveals an interesting fact. All the years where saving was less than would be expected for the given income (as shown by the average line) were years where the time arrows point to the left. That is, they were years with an income lower than that of the preceding year. The years when saving was higher than average, for the given income, were years of *rising* income. Years such as 1924 and 1927, with income little changed from that of the preceding year, fell intermediate between the upper and lower groups. This relation is brought out more clearly by using solid dots to designate the years of rising income, hollow dots for years of falling income, and dots half hollow and a half solid for years with little change. The way in which 1938, with a sharp fall in income, drops to the lower group is quite striking. Fulcher, in a recent study of the savings of individuals,[18] also noticed this difference in the level of the regression line in certain years, but explained it by saying "the urge to save seems to have been greater during 1933-36 than during 1926-32."

It seems clear from this superficial examination that the amount of saving is influenced not only by the size of the national income, but also by the direction of its change. Saving in years of rising income apparently usually runs about 5 billions higher than saving in years of falling income. This suggests a persistence in habits of consumption. Apparently the first effect of a rise or fall in income is to increase or decrease saving. It may be that only after that rise or fall in income has persisted for a time does consumption respond, so that a major portion of the higher or lower income becomes reflected in higher or lower consumption expenditures. This hypothesis is consistent with the facts

[18] Gordon S. Fulcher, "Annual Savings and Underspendings of Individuals, 1926-37," *Rev. of Econ. Stat.*, vol. xxiii, Feb., 1941, pp. 34-35. The diagram in Kalecki's analysis of investment and income is also similar. See Michal Kalecki, *Essays in the Theory of Economic Fluctuations* (London, Allen and Unwin, 1939), p. 71. He made an adjustment for a time lag, relating income of the present year to two-thirds of investment for the present and one-third for the preceding year.

shown in Figure 5 and also with the peculiar type of lag previously pointed out in Figures 3 and 4.

It appears superficially from Figure 5 that the level of saving for any given income is influenced only by whether income is going up or going down, regardless of how fast or slow it is rising. The data for 1928 and 1929, however, with only a moderate rise in income and with saving somewhat below what might be expected from the other rising years, suggest that the rate of increase may also be an influence. The effect of the rapid rise in stock market valuations and of large capital gains realized or imputed may also have been a factor in 1928 and 1929.[19]

The hypothetical relationship with which the data most closely conform can be tested statistically. Three alternative hypotheses may be stated:

1. That there are separate functions for the relation of saving to income in years of rising and falling income, with different slopes for each relation.

2. That there is a constant difference between saving in years of rising and falling income, but that the slopes of the curves are the same for both relations.

3. That the difference between saving in years of rising and falling incomes is a function of the amount of change in income from the preceding year to that year.

The consistency of the data with these three hypotheses was tested, both with and without an allowance for a trend in the propensity to save. In both cases the analysis based on the third hypothesis was found to be the best.[20] The relation between national income and saving, however, came out much the same regardless of which of the three hypotheses was employed in determining it.[21]

[19] See J. M. Keynes, *op. cit.*, p. 319; also O. L. Altman, *op. cit.*, p. 9.

[20] The results of the analyses according to the three hypotheses were as follows:

Per cent of variance in annual saving explainable in terms of the factors considered (adjusted coefficient of multiple determination, $\bar{R}^2_{1.23}$)

Hypothesis tested	Without trend allowance (%)	With trend allowance (%)
Hypothesis 1	84.1	85.6
Hypothesis 2	84.9	86.3
Hypothesis 3	89.2	95.1

Tests of statistical significance show that a superiority of hypothesis 3 over hypothesis 2 as great as shown here would be unlikely to be secured unless there were a real difference in the underlying relationship. Only in one test out of six, on the average, would as great a difference as this be found, if the data were true random samples drawn from the same universe. (For the significance of such sampling criteria with time series analyses, see the author's *Methods of Correlation Analysis* [New York, Wiley, rev. ed., 1941], chap. 19.)

[21] The relevant net regressions were as follows, for the average difference in saving for a one-billion difference in gross national income:

All of the analyses agreed in showing that there was a significant change in the propensity to save during the period, declining to a low during the early thirties, and then turning up again. The analysis selected as the best (the third assumption plus a trend factor) showed a slight but distinct curvilinearity in the relation of saving to income. With higher and higher incomes the additional amount of saving per billion of additional income showed a slight but distinct increase.

These final results are shown in Figure 6, together with the data from which they were computed. The three factors shown explain 96 per cent of the annual changes in saving during the period, and estimate saving for each year with an adjusted standard error of estimate of only 974 millions of dollars.[22]

Figure 6 shows that with each additional billion dollars of gross national income, saving is increased by 265 million dollars on the average, but is ordinarily increased (or decreased) further by 230 million dollars for each billion dollars that income rises above (or falls below) the income of the preceding year. In the first year after gross national income increased by one billion dollars, then saving would usually increase by 495 million dollars while consumption expenditures would increase by only 505 millions. If income remained the same next year, in the second year after that billion-dollar increase consumption expenditures would rise by a further 230 millions and saving would decline an equal amount. The relation of income to saving thus has a dynamic as well as a static component.[23]

Hypothesis 1. 257 millions (when income is rising)
287 millions (when income is falling)
Hypothesis 2. 297 millions
Hypothesis 3. 281 millions

In each case these are the net changes found to be associated, while holding constant the other factors (but not including trend). When trend was also allowed for, the net relation (for the third hypothesis) was found to be a difference of 265 millions in saving for each billion in gross national income.

[22] The exact values were: $\bar{P}^2_{1.2345} = 0.959$; $\bar{S}_{1.2345} = 974$ millions.
The linear regression equation determined was

$$X_1 = .265\,X_2 + .230\,X_{2_{(1-0)}} - .797t + .032t^2 - 3.112.$$

An analysis using as the dependent variable saving a percentage of income and substituting the annual percentage increase or decrease in income gave slightly better results than the one shown here. The difference, however, was not significant. Consequently, the simpler analysis is shown here. An analysis using data corrected for price and population changes gave a coefficient of multiple determination ($\bar{R}^2_{1.2345} = 0.948$) lower than the analysis pictured in Figure 6 and discussed in the text.

The curvilinear net regression of saving upon income, as shown in the upper section of Figure 6, is consistent with the corresponding net regression as determined from the analysis based upon the percentage of income saved. In so far as the data charted in Figure 6 are concerned, however, the increase in correlation obtained by using the curve instead of a straight line has no statistical significance.

[23] W. S. Salant in *The Magnitude of the Recovery Problem* (mimeo. pub., Dept. of Commerce, 1940), allowed for this dynamic element by introducing the annual change in

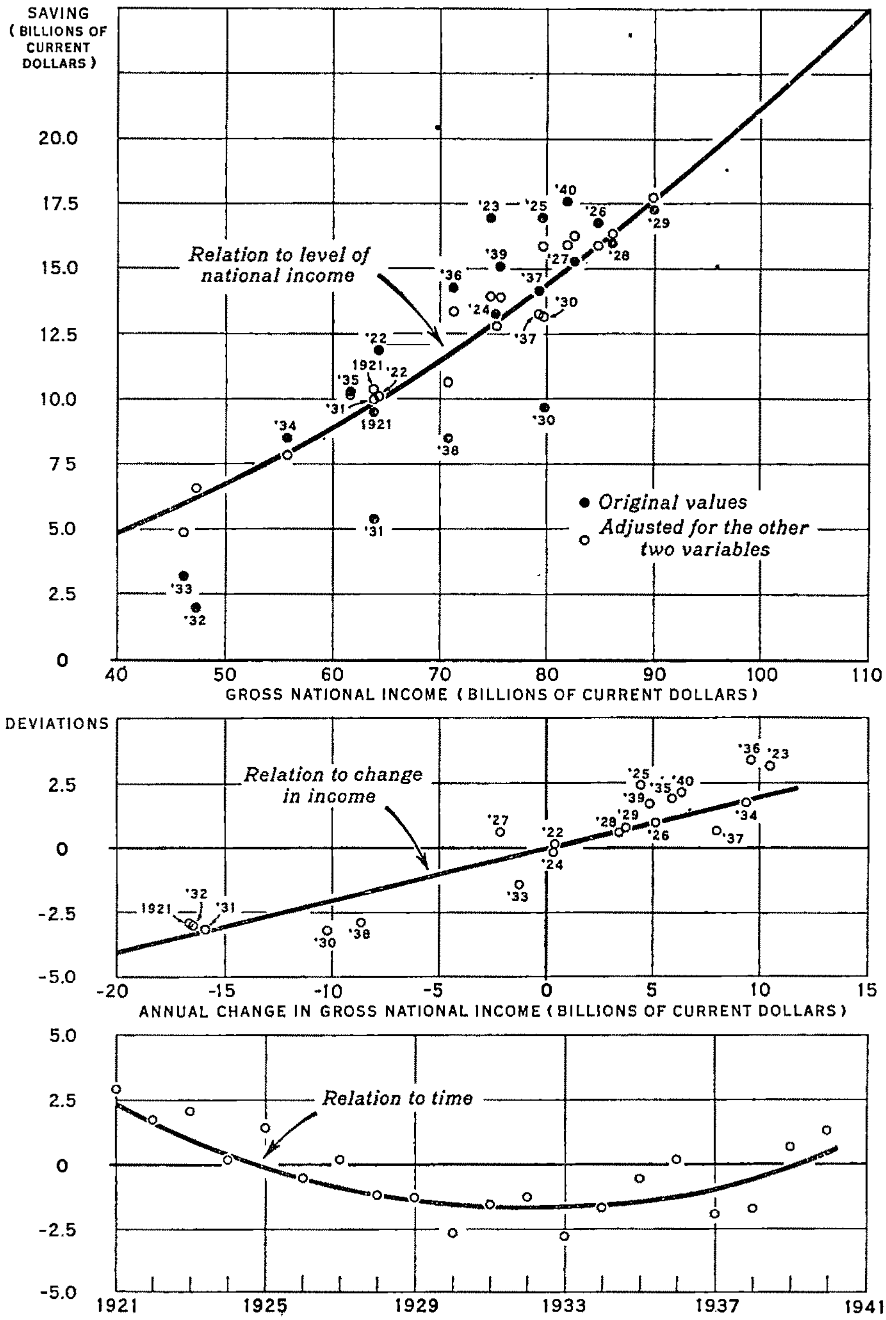

FIG. 6—Factors Relating to Saving, 1921-40.

With respect to this dynamic factor in saving (and to similar dynamic factors in investment, which will be developed in the second paper of this series), Keynes comments:

> I have endeavored to deal with a good many of the sort of problems you have under consideration by regarding the multiplier during a dynamic period as being lower at first when there is an unforeseen increase in permanent investment with a subsequent return to its normal figure. This may be important in time of war, when the first phase may be prolonged almost indefinitely through the inability of supplies of consumers' goods to respond to increased demand.
>
> For when there is an unforeseen increase in permanent or *quasi* investment, it is for a time, and perhaps for a long time, physically impossible for the increased purchasing power of the public to result in increased consumption, however much they may desire this. For there will be no increase of consumers' goods available except to the extent that stocks can be drawn upon. So that the purchasing power has either to spill itself in higher prices or be accompanied by a change in the propensity to consume which diverts more of it for the time being into saving.[24]

The relation of changes in the income level to saving—the dynamic factor—also raised an interesting question as to the significance of the consumption-saving patterns shown by the Brookings and the National Resources Committee estimates. The latter, in particular, are based upon 1935-36 data. In those years (note Figure 6) the *increase* in income was large, and about 2 billions of the saving was explained by that increase. Presumably this was distributed through the consumption and saving of the various income classes. When the 1935-36 distribution is used to estimate probable saving and consumption at still higher incomes, this dynamic factor may be intensified. The Kneeland estimates may therefore not serve as a safe guide to the probable level of saving when a given level of income is maintained statically, but only when that level is being reached on a forward movement. Direct comparison of the Kneeland estimates with the estimates of saving based upon the analysis above do not, however, support this suspicion that the Kneeland estimate is biased upward for static conditions.

---

income as a factor in a statistical analysis of gross capital formation and gross national product. So far as is known, this is the only case prior to the present study where the dynamic factor was explicitly allowed for in this way. As suggested by Salant in a letter to the author, the weighting technique used by Currie (see Hearings, *op. cit.*, p. 3536) and Kalecki (*op. cit.*, p. 73) was a rougher way of taking into account the dynamic element. The two methods are identical mathematically in the sense that one form can be transformed into the other. G. Colm and F. Lehmann, in their article "Public Spending and Recovery," *Social Research*, May, 1936, pp. 129-66, also assume a changing propensity to save in their statistical analysis. In their attempt to measure the primary and secondary effects of public spending leakages have been assumed as decreasing from 50% to 33⅓% (see p. 143).

[24] See also, Keynes, *op. cit.*, p. 125, and D. H. Robertson, "Notes on Mr. Keynes' General Theory of Employment," *Quart. Jour. of Econ.*, 1937, p. 168.

The curvilinear relation between national income and saving (with changes in the level of income held constant) deserves special comment. As plotted in the upper portion of Figure 6, this shows a relation as follows:

Level of Gross National Income (in billions)	Corresponding Level of Saving with National Income Unchanging from Year to Year[a]	
	Amount (in billions)	Per cent of total
45	5.75	12.8
55	7.75	14.1
65	10.20	15.7
75	12.80	17.2
85	16.00	18.8

[a] Holding trend constant at the 1939 level.

Apparently the normal addition to saving for each billion added to the static level of gross national income shifts from about 200 millions between a 45- and a 55-billion level to about 320 millions between a 75- and an 85-billion level. These normal saving levels are also of interest for the relative amount.

The trend shown in the lower section of Figure 6 indicates that the propensity to save declined steadily during the 1920's and turned up slightly in the late thirties.[25] With the same national income, saving in the early thirties would apparently have been about $1\frac{1}{5}$ billion dollars less per annum than in the early 1920's. These changes in the propensity to save may have been associated with speculative income and capital gains, with changes in population rates, with changes in tax policy, or with changes in the concentration of income.[26] The level of the housing cycle may also have been associated with these changes in the propensity to save.

The Functional Relation of Consumption and National Income

Data on consumption are available which are largely independent of the data on saving used in the preceding analysis. This fact makes it possible to make an independent check on the conclusions reached thus far by analyzing the consumption-income relationship.

Theoretically, one would expect to find that the relation of consumption to income was complementary to the relation of saving to income. The relation of consumption to gross national income should be

[25] The trend shown is a second degree parabola, fitted mathematically while holding constant the net linear effects of the other two variables. After the curvilinear adjustment for the first variable was added, tests by the graphic method showed no measurable shift in the type or position of this trend.

[26] Statistical tests of the significance of the factors mentioned showed no measurable relation with changes in saving.

at each stage just the reverse or the reciprocal of the relation of saving to income.

It would be possible to base the analysis of the consumption-income relationship on a figure for consumption derived from the figures used earlier on gross national income and on gross saving. If that were done, there would be no independence in the two analyses and the new analysis would agree perfectly with the previous conclusions. Fortunately, however, Kuznets' estimates of the composition of national income have provided largely independent data on consumption and the analysis may therefore be based on these independent consumption data.[27] Kuznets' estimates of national income are not comparable with the estimates of gross national income used in the study of the offsets to saving data. Consequently, the results of this consumption-income

TABLE III—TWO ESTIMATES OF CONSUMERS' OUTLAY, AND GROSS AND NET NATIONAL INCOME, BY YEARS, 1920–40

Year	Consumers' Outlay[a]	Consumers' Outlay[b]	Gross National Income[c]	Net National Income[b]
	(billions)	(billions)	(billions)	(billions)
1920		62.1		73.5
1921	54.3	55.8	63.8	59.1
1922	52.4	56.1	64.3	60.6
1923	57.8	62.8	74.8	71.4
1924	61.9	66.0	75.2	71.9
1925	62.7	66.6	79.7	75.9
1926	68.0	72.2	84.8	81.4
1927	67.4	71.8	82.7	79.9
1928	70.2	74.2	86.2	81.6
1929	72.7	77.1	90.0	87.1
1930	70.1	73.1	79.8	77.3
1931	58.5	60.2	63.9	60.3
1932	45.4	47.2	47.4	43.0
1933	39.8	45.9	46.2	42.3
1934	47.3	52.2	55.8	49.6
1935	51.4	53.7	61.7	54.4
1936	57.1	57.6	71.4	62.9
1937	65.2	64.1	79.4	70.5
1938	62.3	62.5	70.8	65.4
1939	60.5	—	75.7	—
1940	64.4	—	82.0	—

[27] S. Kuznets, *National Income, 1919-1938,* Occasional Paper No. 2, Nat. Bur. of Econ. Res., Apr., 1941. An adjustment for 1938 and an estimate for 1939, based upon Department of Commerce figures, were made in the analysis.

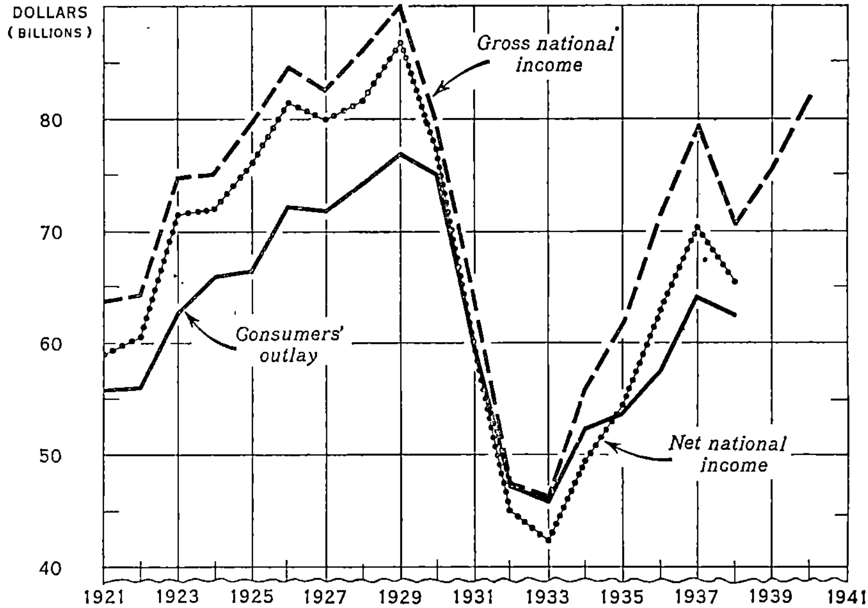

FIG. 7—Consumers' Outlay, and Net and Gross National Income, 1921-40.

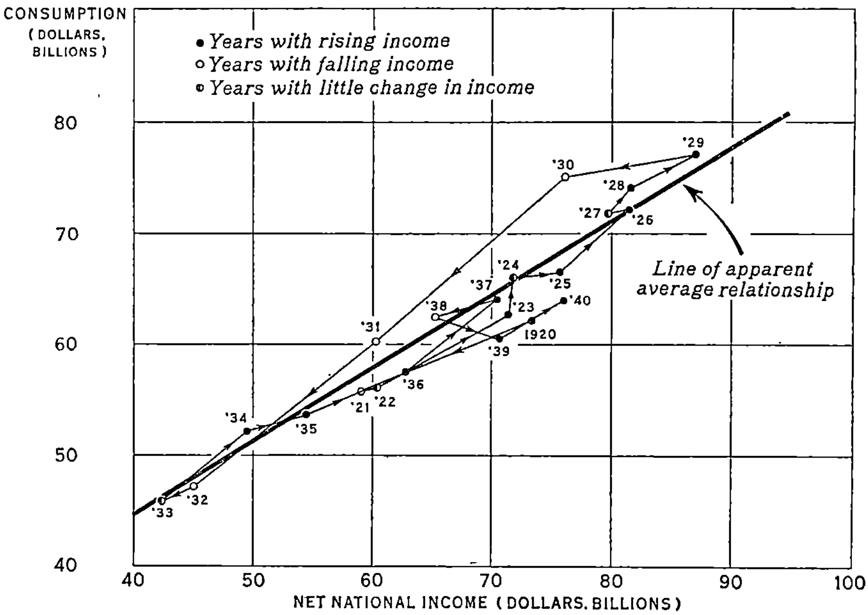

FIG. 8—Correlation of Consumption and Net National Income, 1920-40.

study cannot, strictly speaking, be compared with the results of the previous saving-income study, but they do provide a check upon the conclusions reached as a result of the previous analysis.[28] The estimates of consumption include not only expenditures for non-durable consumers' goods, but also expenditures for consumers' durable goods with the exception of housing which is considered as belonging in the investment category. Some of the goods thus classed under "consumption" are in fact bought through the use of consumers' credit. Consumption as here defined is therefore the same as that shown in Column III of Figure 1.

The changes of consumption in time, as compared with the changes in gross and net national income, are shown in Figure 7. Consumption at all times absorbs the bulk of national income, so it necessarily has a close correlation with it, as is evident in the figure. The nature of this relation is shown more clearly when consumption and net national income are plotted against one another on a dot chart (Figure 8). The relationship is close and apparently linear. It would be possible to explain consumption in every year from income alone with no error greater than 5 billion dollars, and in most years with errors no larger than 2 billions. The simple relation of income to consumption is thus closer than was the simple relation to saving, shown on Figure 5.[29]

Closer examination of Figure 8, however, reveals some of the same peculiarities seen in Figure 5, or, rather, their reverse. Certain years show relatively high consumption for the current income: 1930, 1931, and 1938. These were years of *falling* income. Other years show relatively low consumption for the current income: 1921, '22, '23, '25, '36, '37, '39, and '40. These were mainly (though not entirely) years of *rising* income. There is also some trend present, apparently, with consumption in the latter years of the twenties relatively high and in the latter years of the thirties relatively low. These differences in the behavior of consumption are consistent with those noticed earlier for saving. Rising income is apparently accompanied by less consumption and more saving than would be expected after a static balance is attained at the higher income; falling income by more consumption and less saving than in the static situation.

The relations shown in Figure 8 may be analyzed by the same methods used in analyzing the income-saving relations of Figure 5. Going at once to the type of relationship which was found to yield the best results for saving, we may apply it to consumption by using the formula:

[28] For a discussion of the differences between the two income series the reader is referred to Altman, *op. cit.*, p. 14, footnote 3.

[29] This checking of the saving function by study of the consumption function was suggested to the author by Alvin Hansen. Compare the results shown here with those in Hansen, *op. cit.*, chap. 11, appendix by P. A. Samuelson.

$X_1 = a + b_2X_2 + b_3X_{2_{(1-0)}} + b_4 t + b_5t^2$

where X_1 = consumption, in billions of current dollars

X_2 = Net national income in billions of current dollars.

$X_{2_{(1-0)}}$ = Change in net national income from preceding year in billions of dollars.

t = time in years.

The inclusion of t and t^2 in the formula makes it possible to include allowance for a trend in the propensity to consume, with a parabolic curve.

Fitting this equation by multiple correlation gives the values for the parameters as follows:

$$X_1 = 10.256 + 0.712X_2 - 0.090X_{2_{(1-0)}} + 0.917t - 0.37t^2$$

The closeness of fit of consumption as estimated from this equation to the actual consumption is even better than were the corresponding estimates for saving.[30]

The relations as fitted in the equation just given are compared with the original observations in Figure 9. The solid dots in the upper portion of the chart show the original values; the hollow dots in each section show the values after adjustment for the relationship to the other variables. Inspection of this figure shows no perceptible curvilinearity in the relation of consumption to either the level of income or to change in income. If consumption rose by a decreasing amount as the level of income rises, that would be shown by a curve for the upper line, convex from above. The hollow dots give no significant indication of such a curve.

The lower portion of Figure 9 shows the nature of the net trend. Apparently the propensity to consume increased gradually during the twenties, reached a high early in the thirties, and then declined thereafter. The adjusted data for the individual years indicate that this parabolic trend fits the observations quite satisfactorily.[31]

When Figure 9 is compared with the corresponding figure for saving, Figure 6, the similarity is striking. Both saving and consumption rise with the level of income. The difference between income and consumption at any given level of income is quite close to the indicated saving at the same level. Thus, at 60 billions net national income or about

[30] After allowing for the degrees of freedom removed, the adjusted values were $\bar{R}^2_{1.234} = 0.986$, $\bar{S}_{1.234} = 1.044$. This relation to income and trend thus explains over 98% of the observed variance in consumption. An analysis using data corrected for price and population changes gave a coefficient of multiple determination much lower ($\bar{R}^2_{1.2345} =$ .952) than the analysis pictured in Figure 9.

[31] Tests of the significance of the addition of the trend indicate that it raises the total correlation by an amount that would occur by chance only in one sample out of eight if the samples were drawn from a universe where trend had no real significance.

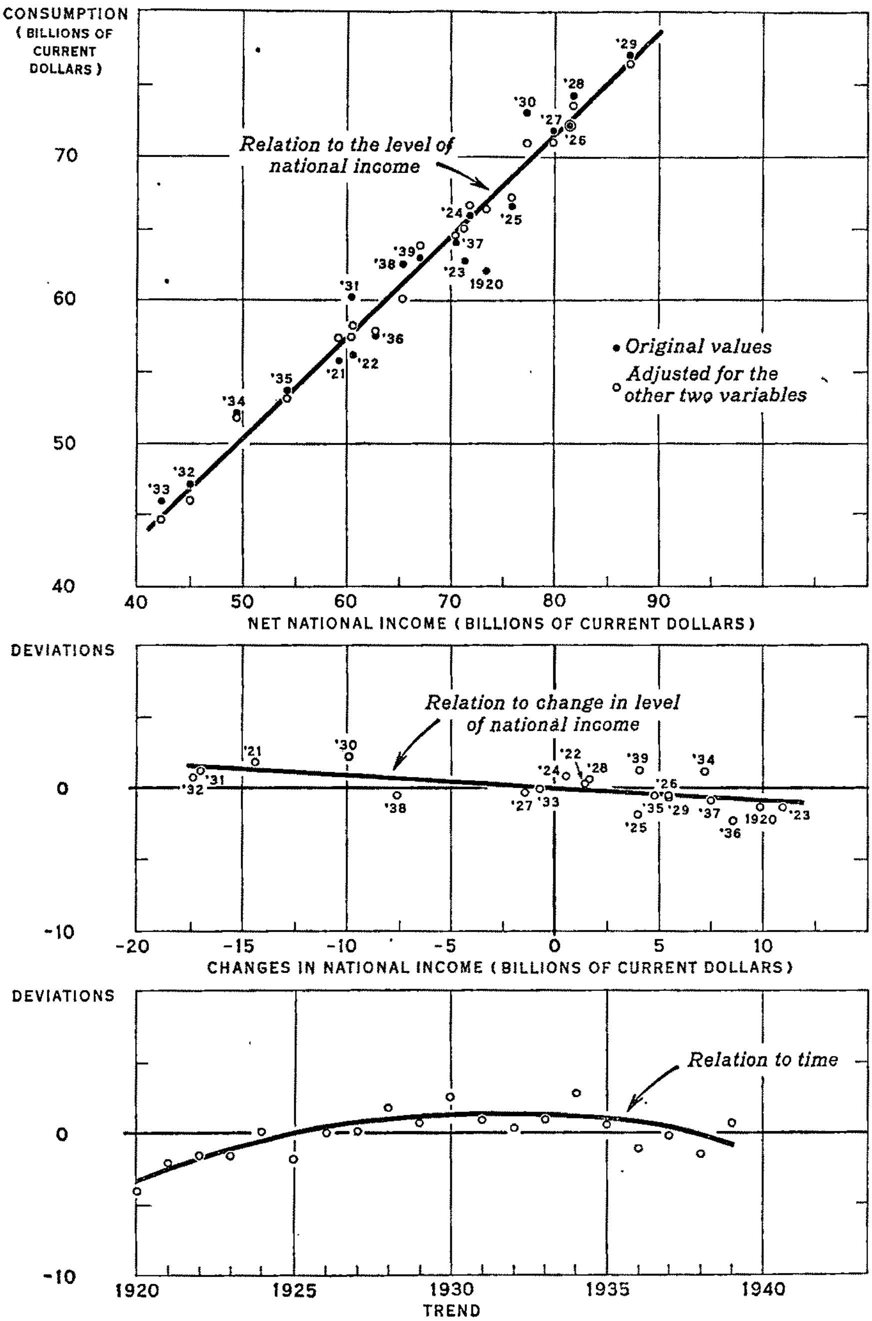

FIG. 9—Factors Related to Consumption, 1920-39.

65 billions gross, the difference is about 8 billions (from Figure 9), and saving is almost 10 billions (from Figure 6); at 75 billions net national income or 80 billions gross, the difference is 12 billions, and saving is 14 billions.[32] But saving (Figure 5) and consumption (Figure 10) show reverse relations both to *change* in level of income and to time. This is in accord with our theoretical expectations and with the apparent relations as shown on Figure 8.

The trend functions are the reverse of one another in shape and timing and in magnitude. Thus, Figure 6 shows that saving in the early twenties ran 2.5 billions above the average amount expected with the current level and change in income, whereas Figure 9 shows that consumption ran in 1921 about 2 billions below the average consumption expected with the current income.

The relations of saving and of consumption to the *change* in income, however, do not come out of the same magnitude. Figure 6 shows each billion dollar *change* in income level to be accompanied by a 230 million increase in saving above that otherwise expected; while Figure 9 shows each billion dollar *change* in income level to be accompanied by only a 90-million decrease in consumption below that otherwise expected. Furthermore, the static relation of consumption to the income level shows no sign of the curvilinearity evident in the static relation of saving to the income level.

These statistical discrepancies in the relations may be explained in part by the differences in the make-up of the consumption and saving and income series, already referred to. The inclusion in the consump-

[32] Figure 9 is computed with net national income as the independent variable, and Figure 6 is computed with gross national income as the independent. To compare the two, it is necessary to use the amount of gross national income usually equivalent to a given net national income. Using the average relationship, this is as follows:

Net National Income (in billions)	Corresponding Gross National Income (in billions)
60	65
75	80

Entering the upper grids of Figure 6 and Figure 9 with these values, the results are as follows:

From Figure 6:

Gross National Income (in billions)	Amount of Saving (in billions)
65	10
80	14

From Figure 9:

Net National Income (A) (in billions)	Corresponding Gross National Income (B) (in billions)	Amount of Consumption (C) (in billions)	B–C (in billions)
60	65	57	8
75	80	68	12

tion series of certain items of durable goods tends to dampen down the response of consumption to *change* in income.

In periods of rapid change in the level of consumers' income, two forces seem to be at work. These two affect the propensity to consume in opposite directions. On the one hand, habits of consumption in individual families seem to be more persistent than habits of saving, so that sudden or large changes in income do not at first affect expenditures for current consumption proportionately, and do affect savings more than proportionately. After a time, if the new level of income is maintained, consumption habits are readjusted upwards or downwards to the higher or lower levels, and savings then are adjusted to conform to the new levels of consumption expenditure.[33] Expenditures for consumers' durables, on the contrary, behave in a different manner. Periods of rising income encourage consumers to expand their purchases of durable goods. This may occur both through the expenditure of idle funds or previous savings, or through purchase on installment credit. In periods of falling income, expenditures for consumers' durables can fall very sharply, while purchases on credit decline below the level of payments due on past purchases, resulting in negative expenditures for durable consumers' goods on credit. The statistical data on this last point are very clear, changes in consumers' credit (which is largely on durable goods) being explainable 95 per cent by *changes* in income, and only 5 per cent by the *level* of income. (Note Figure 10.)

The dynamic relation of an increase in income to consumers' expenditures is thus twofold: expenditures for current consumption rise by less than would be expected from the static relation of income to consumption, while expenditures for consumers' durables other than housing rise by more than would be expected from the static relation. Of the two elements, the changes in current consumption expenditures apparently dominate, as when all consumers' expenditures, durable and non-durable, are lumped together, the net result is a *smaller* dynamic change in consumption (Figure 10), and a *larger* dynamic change in saving (Figure 6), than would be expected from the static relations with income. To the extent that our statistical classification has included in consumption some of those components of consumer expenditures which are financed by installment credit, and are of semi-

[33] In an earlier study, Dirks pointed out very clearly the probable differences in the dynamic and static effects (as they have been termed here) of income changes, and called attention to the "inertia or stability of living standards in the wage-earning classes," and supported it by the analysis of German data. The statistical method which he employed, comparisons of rate of change in both series, lagged and concurrent, did not, however, enable him to measure separately the dynamic and the static elements in the relationship. See Frederick C. Dirks, "Retail Sales and Labor Income," *Rev. of Econ. Stat.*, vol. xx, no. 3, Aug., 1938, pp. 128-34.

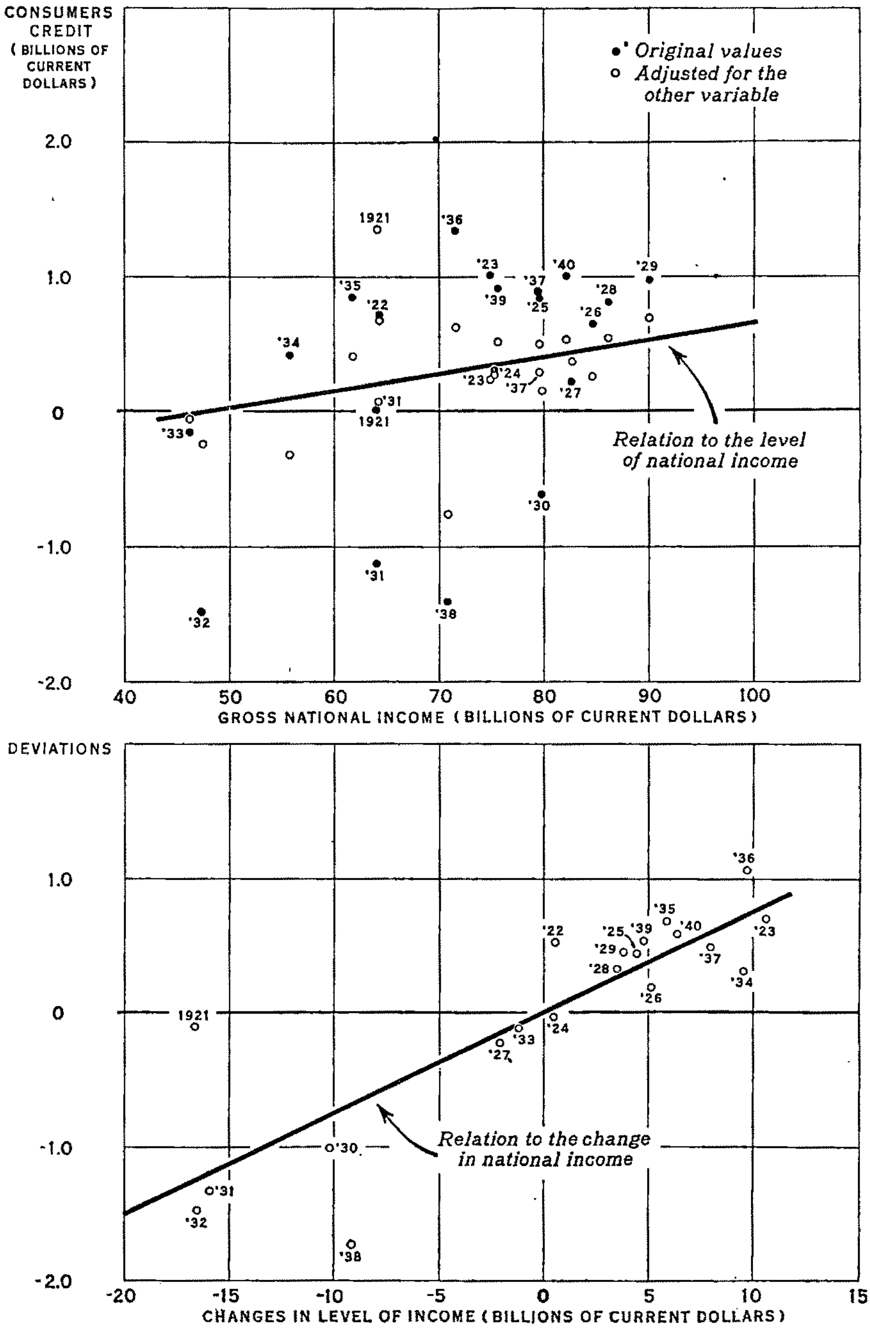

FIG. 10—Factors Related to Consumers' Credit, 1921-40.

durable or durable nature, it has thus concealed part of the response for the current consumption items to the *change* in income.[34]

The way in which the data are conventionally organized thus tends to obscure some of the elements of actual economic behavior. All expenditures for one consumers' durable goods—housing—are usually classified with commercial investment, whereas expenditures for other consumers' durables are classified, in whole or in part, with expenditures for consumption.[35] Yet in many respects expenditures for consumers' durables behave quite differently from expenditures for other consumption goods, and in the dynamic sense they react in an opposite direction. These facts suggest that a breakdown of gross national product might be developed which would base the classification more on similarity of behavior, and less on the commercial or non-commercial character of the expenditures, than do the existing breakdowns.

Relation to institutional changes

The analyses to this point have shown something of the nature of the functional relations between income and saving and consumption. The saving function and consumption function thus defined represent saving and consumption habits under the conditions prevailing during the period covered by the base data—the two decades of the period 1921-40. As a whole this period was one of relatively low taxes on income,[36] of continuing expansion in saving through institutions such as life insurance concerns, of large amounts of saving by business institutions, and of large capital expenditures by governmental bodies.[37] The period as a whole was also marked by high levels of production in two items of consumers' capital, housing and automobiles. Purchases on

[34] This conclusion was verified by a further statistical analysis of consumption. In this analysis, the data on consumption were corrected by subtracting from them the changes in consumer credit, thus giving a measure of consumption expenditures from current income alone. The three independent factors explained 98.4 per cent of the variance in this new consumption figure. The relations to total income and time were similar but the relation to change in income was much more marked. Thus analyzed, the dynamic relation of income to consumption comes out very close to the reverse of the dynamic relation of income to saving, as would be logically expected. Figure 6 shows that for each one billion dollars that income one year rises above the income of the preceding year, saving increases 230 millions above the saving expected at the new income level. Consumption (excluding purchases based on consumer credit) declines 167 millions *below* the consumption expected at the new income level.

[35] The distinction between durable and non-durable consumers' goods is based on duration of life in ultimate use. For discussion see S. Kuznets', *Commodity Flow and Capital Formation*, vol. I (New York, Nat. Bur. of Econ. Res., 1938), pp. 5-7.

[36] Thus the average effective rate on a net income of $25,000 ran between 5 and 10 per cent during most of this period and never exceeded 15 per cent. Approximately 60 per cent of all saving by individuals is done by those with incomes of $20,000 and less. Mordecai Ezekiel, "An Annual Estimate of Savings by Individuals," *Rev. of Econ. Stat.*, vol. xix, no. 4, Nov., 1937, p. 183; National Resources Committee, *op. cit.*, p. 48.

[37] Hansen, *op. cit.*, pp. 238-47.

installment payments may themselves influence saving and consumption habits. The distribution of income among individuals remained highly unequal through the period as a whole, with 25 per cent or more of all income disbursed going to the top 5 per cent of income-receivers, and with the bottom 25 per cent of income shared by 55 per cent or more of income-receivers.[38] Throughout the period one-eighth to one-fifth of all individual income payments went to the top one per cent of income recipients.[39]

Presumably the trends shown on Figures 6 and 9 may reflect changes in some of these institutional factors during the period. As indicated earlier, however, no definite quantitative relationships of institutional changes to these trends have been discovered. On the contrary, the downward movement in income tax rates during the twenties and the increases in the thirties, would be expected to produce shifts in saving and consumption habits just the reverse of those which were actually observed.

A study of the degree of concentration of income in the higher brackets shows that changes in this factor are closely associated with changes in national income. To the extent that this is true the effect of this factor upon saving and consumption is already measured in the relations to the level of income and the changes in that level. No significant net relation was found when this factor was added to the analysis.

It is important to emphasize that the quantitative relations shown apply only under the particular institutional and historical conditions for which they were measured. Before these relations could be used to reach judgments for earlier or later periods, they would have to be adjusted to allow for concurrent changes in all the numerous factors that may influence distribution of national income and saving and consumption habits. However, barring sudden institutional changes of great magnitude, such as the overthrow of our private enterprise system, and assuming the continuity of the trend, the relations determined here seem to describe adequately the behavior of saving and consumption and could be extrapolated for short distances without an undue amount of error.

Summary

This paper analyzes the relation of saving to income and of consumption to income under the conditions which prevailed in the United States from 1921 to 1940, while eliminating (holding constant) the

[38] National Resources Committee, *Consumer Incomes in the United States* (Washington, Government Printing Office, 1938), p. 6; and Leven, Moulton, Warburton, *op. cit.*, pp. 228-29.

[39] A. Goldenthal, "Concentration and Composition of Individual Incomes, 1918-1937," *T.N.E.C. monog. no. 4* (Washington, Sup. Doc., 1940), p. 16.

influence of other factors, found to be related to saving and consumption. Income and changes in income were found to be the major factors related to movements in saving and in consumption. The analysis of the relation of gross saving to gross income confirms the analysis of the relation of consumption to net income. Both analyses show that as national income increases from low levels to high, at the higher levels proportionately more is saved and less is consumed than at the lower levels. Both show that there have been changes in this relation during the past two decades, with consumption at a given income reaching its maximum and saving at a given income its minimum, in the early years of the thirties. Both show that there is a dynamic factor in the relationship with large *changes* in the level of income being accompanied at first by larger changes in saving and smaller changes in consumption than prevail subsequently after a new static balance has been established.

Both the saving-income relation and the consumption-income relation were continuous at approximately the same level through the decade of the twenties and that of the thirties. The trend element showed no sharp break between these periods, and the functional relation remained the same.

The relations found between saving and income and consumption and income, static and dynamic combined, plus the long-time trend in each, left only 4 per cent of the variance in saving and 2 per cent of the variance in consumption unexplained.

The dynamic factor, as discovered here on empirical analysis of the behavior of the relations, agrees surprisingly well with the dynamic factor introduced on theoretical grounds by Smithies as part of his "process analysis" in a paper of which I did not learn until after these studies were completed.[40] Substitution of these realistic parameters into his theoretical equations might extend still further the value of his exceedingly promising analysis.

Except for the introduction of the dynamic factor, these conclusions are in general accord with the hypotheses stated at the beginning of this paper.

Dynamic factors aside, they show that consumption increases as national income increases, but relatively slower, while saving increases as income increases, but relatively faster than income.

(Part II will be published in the June number)

"PERMANENT" TECHNOLOGICAL UNEMPLOYMENT

"Demand for Commodities Is Not Demand for Labor"

By Hans P. Neisser

I. Introduction

The theory of technological unemployment is a stepchild of economic science. The facts seem to stand in such blatant contradiction to orthodox doctrine, according to which no "permanent" technological unemployment is possible, that most American textbooks prefer not to mention the problem itself. This attitude is of recent times. The analysis to which Ricardo subjected the displacement of labor by the machine in the last edition of the *Principles* had stimulated a lively discussion among the later classical economists, who, as we shall see instantaneously, followed two different lines of thought. With the rise of neo-classical equilibrium analysis, the discussion died down, at least in Anglo-Saxon literature[1] and only recently the oldest argument against technological unemployment, originally developed by McCulloch, was revised in a little more sophisticated form by two American economists, P. H. Douglas and A. Director in *The Problem of Unemployment* (New York, 1931). We can, therefore, distinguish three approaches:[2]

1. The "Law of Markets" approach, formulated at first by McCulloch in *Principles of Political Economy* (first edition, 1825) Part I, chapter VII, and, as pointed out above, revised by Douglas and Director, applies Say's Law of Markets to the Labor Market. As there cannot be a general over-production of commodities produced, so there cannot be a general over-supply of labor. We shall analyze this argument in the first section of this paper, with some supplementary remarks in Section V.

2. McCulloch's argument was not taken up by the other classical authors, because it is at variance with the classical theory of the demand for labor. As John Stuart Mill stated it most pointedly: "Demand for commodities is not demand for labor" (*Principles,* vol. I, p. 5, para. 9). The maintenance of the demand for commodities according to Say's

[1] Pigou's and Hicks's discussion of labor saving and capital saving inventions was not developed with a view to the unemployment problem. See below, Section V.

[2] The history of the doctrine in question has been written, in a scholarly fashion, by Alexander Gourvitch, *Survey of Economic Theory on Technological Change and Employment* (Work Projects Administration, National Research Project, Report No. G-6, Philadelphia, 1940). The present approach differs in many respects from Mr. Gourvitch's one.

Law, therefore, does not militate against an over-supply of labor. It is the volume of circulating capital, interpreted as wage fund, that governs the demand for labor. Following Ricardo's lead, the theory of "compensation" of technological displacement of laborers was worked out. In contrast to the Law of Markets approach, which does not allow any exceptions to the denial of "permanent" technological unemployment, the Wage Fund School maintains the occurrence of compensation only as the general rule, exceptions from which are deemed possible though unlikely. In Section III,[3] we shall consider this argument.

3. The neo-classical equilibrium approach differs from the preceding ones by denying the possibility of technological unemployment only as to a state of long-run general equilibrium proper, in which complete adjustment of all the variables of the economic system is attained (size of firm, input, output, prices of goods produced, prices of productive services, interest rate). The difference of the neo-classical approach from the Law of Markets approach is concealed by the use of the terms "temporary" and "permanent" by the latter school. By "permanent," Douglas and Director do not refer to the state of long-run equilibrium proper. This is clear from their definition of "temporary" technological unemployment (*op. cit.*, pp. 113 *ff.*), which refers only to such obstacles to the reabsorption of laborers as: slow working of competitive mechanism, slow transfer of expenditure from one good to the other, or of workers from one industry to the other. A state of affairs in which these obstacles are overcome (as we shall assume throughout the present paper) still might be in a merely "short-run equilibrium" in the neo-classical sense, which is based on the assumption that all equipment is "given" as to quality and quantity, while long-run equilibrium proper in the neo-classical sense requires, among other things, the adjustment of the size of the firm and of the quality of equipment in such a way that average costs equal price for all firms. Indeed, if the Law of Markets is valid at all, it must be applicable to periods of any length, provided only the period is long enough to overcome the temporary obstacles; and similiar considerations apply, as we shall see, to the wage-fund argument.

There is a further important difference between the scope of the neo-classical argument and the two preceding ones. Their concepts of unemployment differ. The older theories use something like the popular concept: a man is called unemployed if he cannot find employment at the prevailing wage rate. If "permanent" technological unemployment in this sense is impossible, then, indeed, technological progress would confer only benefits to the working class, as maintained by the two classical schools. On the other hand, the neo-classical approach only

[3] Section II deals with the concept of a labor-saving device.

maintains that, in the long run, a man can always find employment at the *long-run equilibrium wage rate*, which may differ considerable from the prevailing rate. A man who refuses to work at this equilibrium rate might be called unemployed by the classical school, but would not be called unemployed by the neo-classical economists; it is in this sense only that neo-classicism denies the possibility of "permanent" unemployment.

While there is little merit in the two classical approaches, the neo-classical one stands on much firmer ground, on account of its lesser scope. However, even the neo-classical approach is far from giving the unambiguous answer its adherents ascribe to it. This will be shown in Section IV. On the other hand, while the unqualified denial of "permanent" technological unemployment in traditional theory is not justified, preliminary empirical investigations (which cannot be presented in the present paper) have convinced the present writer that popular opinion vastly exaggerates the amount of unemployment which properly could be called "technological." The relative small size of technological unemployment in history is attributable, partly, to the independent forces increasing employment, which briefly will be discussed in the last section. In no case would it be permissible to use simply the current unemployment statistics as a verification or a repudiation of the theories which affirm or deny the existence of technological progress that creates unemployment. Hitherto the discussion has been marred by a confusion of historical and theoretical statements. We read, *e.g.*: "As a matter of fact, however, the increased output, consequent upon the introduction of machinery, gave rise to an increased demand for products; and the increased products, due to the cheaper machine process, stimulated the accumulation of capital and resulted in the building and operation of numerous new plants which reabsorbed the labor supply. Thus machinery in the end has not displaced labor but instead has increased the marginal product of labor and thus increased real wages."[4] We may interpret this as a historical statement concerning the period since the Industrial Revolution till the crisis of 1929; during this period, factors making for more employment are supposed to have outweighed the factors of displacement; and this historical statement is, of course, confirmed by the inspection of census figures. On the other hand, these statistics are quite inappropriate to the theoretical question whether technological progress *contributes* to unemployment. What would one think of an argument against the law of gravity based on the undeniable truth that only a very small number of people habitually fall against the center of the earth with an acceleration of 33 feet per second? And yet, the reference to unanalyzed observation is not worse than the reference

[4] F. B. Garver and A. H. Hansen, *Principles of Economics* (1937), p. 567.

to unanalyzed historical facts. In order to obtain a reliable answer to our question, it is necessary to keep constant the other factors as far as they are *truly independent, i.e.,* not exclusively or almost exclusively governed by the volume of technological unemployment itself.

II. The Law of Markets Approach

The compensation argument of the Law of Markets School runs as follows: Purchasing power is, by itself, indestructible; if technological progress in industry A reduces the amount of labor necessary to produce a given volume of output in this industry, the price of the goods will decline in proportion to the decline in average costs, at least under conditions of full competition; now either the sales volume can be increased correspondingly to the price fall (demand elasticity $= 1$), then the workers displaced will be reabsorbed by the industry A itself, which now produces more; or the sales volume increases by less (demand elasticity < 1), then the consumer will be able to increase his outlay for the products of other industries B, C . . . , which, therefore, would reabsorb the workers displaced in industry A. And in the case of a demand elasticity *larger* than unity it would be industry A which attracts additional labor. Thus, the initial displacement of workers in industry A is compensated by an increased demand for labor either in that industry, or elsewhere. In other words, with a given volume of consumers' outlay and with a given output, a definite amount of employment is associated; demand for commodities *is* demand for labor.

It is difficult to obtain a clear idea of the price theory which underlies this argument. The starting point of the Douglas-Director analysis obviously is a state of *long-run equilibrium* in which not only marginal costs but also average costs equal price; and the analysis ends by looking at *another* state of equilibrium, reached after the technological progress has materialized, because the authors assume that at the end of the process competitive prices will *again* equal average costs. The question naturally arises: In what way is the reabsorption of displaced workers in industries B, C . . . carried through? (For the sake of simplicity, attention will be focused in the present section on the case of a demand elasticity smaller than unity.) In the "short run," *i.e.,* with equipment given as to quantity and quality and with a given wage level,[5] there is no reason to assume that an upward shift of demand in industries B, C, etc., would spend its force exclusively on output. On the contrary, as the basic equation of monetary theory is usually interpreted,

[5] The second condition is not strictly Marshallian and could be dropped in other applications of the short-run concept. As pointed out by F. H. Knight (*Risk, Uncertainty and Profit,* pp. 142-44, footnote), Marshall neglected to correlate clearly the theories of commodity prices and factor remunerations for the different phases because he was concerned chiefly with partial equilibrium analysis.

an increase in the flow of purchasing power may raise *prices* rather than *output*. And although this statement refers to the *total* flow in the economic system and to the price level, it may be true also for an individual industry; for the entrepreneur cannot possibly ascertain the source of rising demand; whether it is generated, on the one hand, by gold production, credit expansion, dishoarding, etc., *i.e.*, factors that govern the flow of purchasing power in general, or, on the other hand, by a redistribution of the *existing* flow. We admit, however, that this application of the "equation of exchange" is not permissible in the problem before us; because even in the short run the physical volume of output is not a given magnitude (as assumed by the older forms of the quantity theory) but is indicated by positively sloped supply curves. Only in the limiting case ("full" utilization of resources) will demand intersect the supply curve in the *vertically* sloped segment of the latter; but there is no case in which the effect of the expanding demand would be wholly concentrated on output, as the theory of compensation implies. Even under imperfect competition, where the competitive supply curve has to be discarded, the cases are rare in which expanding demand will not raise the price.

As long as the equipment in industries B, C, etc., has not undergone fundamental changes as to quality and quantity, they are not able to reabsorb completely the workers displaced in industry A. This adjustment of the given stock of equipment is not discussed at all in this context by the Law of Markets School; and, indeed, the adjustment could not be secured by the operation of the Law of Markets alone. The adjustment can be achieved in various ways: (1) by a change in the size of the firm, other firms changing commensurately in the opposite direction; (2) by a change in the wage level, caused by the technological unemployment; (3) by a change of the "quality" of equipment; (4) by a change in the total quantity of equipment in the economic system. Of these methods, number (1) could not, in principle, raise employment *in toto*, because an increase in the size of one firm, under stationary conditions, involves a reduction in the size of another firm, from which capital is transferred to the first one; nevertheless, the implications of this re-distribution of capital deserve comments; we shall return presently to them. It is mainly the action of mechanisms (2)-(4), not the "indestructibility of purchasing power," through which displaced workers may be reabsorbed. However, as shall be pointed out in later sections, the effectiveness of these mechanisms has theoretical and practical limits which militate against the hard and fast theoretical proposition that no permanent technological unemployment is possible.

The neglect of the mechanisms numbers (2) and (3) by the Law of Markets School can be explained, partly, by their second assumption

that not only consumers' outlay and output, but also output and employment are rigidly associated. In other words, an output of, say, $1,000 in industry A is supposed to be associated with the same amount of employment as an output of $1,000 in any other industry (B, C, etc.), materializing during the same period. The significance of this assumption for the Law of Markets approach is obvious; for let us suppose, for the sake of the argument, that $1,000, transferred from outlay for A to outlay for B would spend their effect exclusively on output and not at all on price in B: still it would not follow that the workers displaced in A would be completely absorbed in B, unless the crucial assumption we are discussing now is correct. However, since labor and capital coöperate in different proportions in different industries, $1,000 output will contain different amounts of wage costs and labor in different industries. The assumption is therefore untenable.

It should be noticed that the assumption discussed in the preceding paragraph does not become tenable if, instead of individual industries, "integrated" industries (including the so-called "higher stages" of production, where raw materials and machinery are produced) or the economy as a whole are considered. It is sometimes asserted that differences in the capital-labor ratio of a lower stage are of no significance for the economic system, because capital expenses will be "ultimately" resolved into labor expenses; thus, if in a lower stage of production the capital expense assumes a relatively large share of total expenses, labor expenses are supposed to take a correspondingly larger share on the "higher" stages. But, first of all, the resolution is not one of *all* capital expenses but only of the replacement allowance (for equipment and material) and it is not a resolution into wages alone but into *all factor remunerations*. The reader may consider the following pattern which symbolizes the circulation in two integrated industries differing as to the share of labor expenses in total expenses. In both cases, total expenses on the lowest stage are $1,000. Under the simplifying assumptions that (a) rent, cost-taxes and profits are zero, (b) that the period of turnover of capital is the same in both cases on all stages, the circulation can be represented, in each case, by three columns representing, from left to right, (1) interest, (2) the other capital expenses (to be distributed on the next stage), and (3) wages; the ratio is, on every stage,[6] in the first case $1 \div 1 \div 2$, in the second case $1 \div 1 \div 6$.

In other words, the net output of an economic system may consist,

[6] Since the highest stages are common to all industries the assumption of a constant share of wages in total expenses on all stages of an "integrated" industry is incompatible with the existence of different ratios for different industries on the lowest stage. This does not invalidate the argument. A more realistic example can be found in my paper "Oeffentliche Kapitalanlagen in ihrer Wirkung auf den Beschaeftigungsgrad" in *Economic Essays in Honour of Gustav Cassel*, London, 1933, p. 464.

e.g., of 66⅔ per cent wages and 33⅓ per cent profit, interest and rent, *or* of 86 per cent wages and 14 per cent profit, interest and rent; in the latter case, obviously, employment would be larger, provided we compare systems with the same output and wage level.

CIRCULATION OF EXPENSES IN INTEGRATED INDUSTRIES

Stage	First Case			Second Case		
First Stage	250	250	500	125	125	750
Second Stage	62.5	62.5	125	15.6	15.6	93.8
Third Stage	15.6	15.6	31.1	1.9	1.9	11.8
....	....	....	....	....	....	....
Sum	333	333	666	143	143	857

For the problem of technological unemployment, however, the correction by which we had to qualify the "resolution" theorem, may seem to be less important. We are still in the short-run phase of the problem, *i.e.*, we ask whether absorption of the released labor is possible with a stock of equipment of given quantity and quality; then only those costs which enter into short-run supply price will matter, *i.e.*, *marginal* costs; in their determination interest plays a very small rôle, the bulk of interest being a fixed charge. There is, however, another aspect of the "resolution" process, which further *invalidates the rigid association* between output and employment, supposed by the Law of Markets School. In an industry B with a relatively small share of labor expenses per $1,000 of output, the total amount of *capital expenses* naturally would be larger than in industry A; and this result holds true also for "integrated" industries. But will the capital expenses be currently expended? We may here disregard the question where, in case of a transfer of consumers' outlay from industry A to B, the money would come from to pay out the larger volume of total expenses, which as the example shows may develop in B as compared with A; for the problem is not purely monetary. Are we entitled to assume that the increased replacement allowances in industry B will be used currently for reinvestment and likewise, in case of an imperfect supply elasticity in B, that the ensuing profit increment in B will be spent and invested in its entirety and not hoarded? Obviously *if* some hoarding took place, then the "higher stages" would not benefit in full from the capital expenses (and profits) in the lowest stage, and the reabsorption of workers would meet a further obstacle.

The following alternatives seem to offer themselves as answer:

1. The chances for an increase in current investment and replacement in B are good if the capacity of the industry as a whole is so well

utilized that aggregate profits are above zero or at least not negative. But then the range over which the supply elasticity in B is still considerably above zero, would be rather small, and the transfer of purchasing power from A to B would spend its force largely on *prices*.

2. A large amount of unused capacity in the bulk of *competitive* industries, *i.e.*, a wide range of *elastic* supply, is indicative of latent *deflationary* tendencies. If, therefore, the displacement occurs in an industry where the share of labor expenses is relatively large, the ensuing price fall, indeed, might bring about a rise in *output* in the lowest stage of B, C, . . . without a considerable price rise; but the absorption of labor in integrated B, C, . . . would *not run parallel* to the increase in *output*.

3. There remains the alternative of widespread "monopoly," under the reign of which unused capacity would *not* be indicative of latent deflationary tendencies. However, a stage of widespread monopoly certainly is not conducive to increasing the stock of equipment by investment.[7]

III. A Tentative Definition of Technological Unemployment

We have already obtained some results,[8] though we have still a long way to go. The Law of Markets does not secure the reabsorption of workers; there is no rigid association between purchasing power and quantity of output nor between output and employment. In the latter conclusion the key to the understanding of technological unemployment is to be found: according to different stages of the arts, a given volume of capital tends to combine with different amounts of labor; the

[7] The Douglas-Director discussion of technological unemployment under "monopoly" conditions is not less objectionable than their discussion of the case of competition. Admitting that consumers of A would transfer less purchasing power from industry A to B, C, etc., under monopoly in A than under competition, they insist that the difference is made up from the increased monopolistic profits in A. This amounts to assuming that monopolistic profits can be spent in the same spending period in which they are taken in; in other words, monopoly is considered to secure an automatic increase in the flow of purchasing power per time unit or, what is the same thing, in the velocity of circulation. A detailed discussion of this unfounded assumption is not necessary because it is not essential to the basic argument of the Law of Markets School; moreover, although the *transition* from competition to monopoly certainly would reduce output and employment, no reason is visible why, under monopoly, the *relative* displacement of workers by technological progress would be larger in per cent of the employed than under competition.

[8] The results of Section I were obtained on the level of a "partial equilibrium" analysis. Most recently, Professor O. Lange has made the attempt, to work out, under the same assumptions (given equipment, given wage level) a short-run *general* equilibrium level in form of a system of equations, which would permit to ascertain the repercussions in industry A originating in the induced changes in another industry. The report on Professor Lange's paper (in "Cowles Commission for Research in Economics; *Report of Sixth Annual Conference*, 1940," pp. 68-71) is too brief to allow any judgment whether, on the basis of his model, results of wider scope than worked out above could be obtained.

labor-saving type of technological progress simply raises the amount of capital per worker. The phrase "tends to combine" points to the fact that the trend of technology may be nullified by forces of *adjustment* (mentioned above, p. 54), the discussion of which will be the topic of the last sections of this paper, but these forces do not entitle us to deny the existence of the technological trend itself.

From this viewpoint, a labor-saving device is a method of production which permits production of the same output with less labor than before, either with the same or an increased amount of capital.[9] This definition provides also an answer to the naïve question whether the displaced laborers would not be reabsorbed in the production of the labor-saving device itself. As matter of principle, no increase in the physical volume of capital is necessarily involved in the technological progress; the improved device may not cost more than the unimproved one, and might be financed from depreciation funds; and even if, in a given case the capital embodied in the new device would exceed that embodied in the old one, reabsorption of all displaced laborers is impossible, since otherwise the unit costs of output would not be smaller than before, and no incentive to introduce the new device would exist.

On the other hand, our definition of labor-saving devices has obvious defects. The criterion "capital divided by labor," both measured in terms of prevailing prices, is defined for a firm of given size, measured in terms of *current output;* output and size of the firm, however, may vary, and for different volumes of output, the ratio in question may be different. (We shall take up this question in Section V.)

IV. The "Wage Fund" as Maintaining Employment

For the short-run analysis offered in the preceding sections, the increase of demand in industries B, C, etc., is the causal factor that brings about a short-run price rise and increase in output. The *market price* would rise at once under a stimulus of increased demand, above the *short-run price,* and it would be the response of entrepreneurs to the higher market price that would bring about the short-run increase in output and would lower the market price to the new short-run level. Consequently, in the analysis of short-run price and output, economic theory needs not bother about the question of where the entrepreneur procures the additional working capital: it is the degree by which working capital is provided that governs marginal output in the short run, and not the quantity of output that governs the volume of working capital needed. Whether the entrepreneur utilizes the temporary extra profits, from the rise in market price, or borrows funds to build up the marginal quantity of working capital, is irrelevant; in any case, the

[9] The corresponding definition of capital-saving devices is obvious.

supply price of the additional funds enters the marginal cost function, the shape of which governs the increase in output for any given upward shift in demand in the industries B, C, etc.

Thus, there would not be any reason to treat specifically the procurement of working capital within the framework of our analysis, if it were not for the central position into which classical economists have placed it in discussing technological unemployment: it is in circulating capital and not in the demand for commodities that, in their opinion, the demand for labor resides. Technological progress therefore could not affect the demand for labor but by impairing the stock of circulating capital. This classical proposition needs some comments.

The circulating capital or working capital is considered by classical economists as a stock of wage goods or "wage fund," supporting laborers during the "period of gestation," *i.e.*, till the goods they are just processing have sufficiently "matured" to be consumed. To this construction, it has been objected that workers do not live on a stock of goods, accumulated in advance for the whole period of gestation but largely on a current flow of goods, emanating continually during the period, provided production is sufficiently synchronized. For our present purposes this point is of minor importance, the more so since the continuous coming forth of the flow is conditioned by the perpetual existence of a stock, not of finished wage goods, but of "goods in process." Ricardo based the possibility of technological unemployment or entrepreneurial inclinations to reduce, in the interest of higher profit, the wage fund by converting "circulating" capital into fixed capital.[10] His successors, for a considerable time, identified the question whether technological progress has proved beneficial or not to labor, with the other whether the wage rate would be adversely affected in the course of progress. To answer in the negative, they were satisfied with proving that, at least in the vast majority of cases, the wage fund would not be reduced by technological progress.[11] The theory of employment itself was only indirectly touched upon. It cannot be doubted, however, that, in classical opinion, the mere fact that the "wage fund" was maintained, sufficed to secure also re-employment of the displaced workers.[12]

The wage-fund theory of employment can serve as an illustration of Marshall's dictum that many an older economist "did not seem to have a sufficient responsibility . . . for keeping the number of his equations

[10] David Ricardo, *Principles of Political Economy and Taxation,* chap. 31.

[11] See the most elaborate analysis of N. W. Senior, *An Outline of the Science of Political Economy* (Reprint, 1939), pp. 153 *ff.*

[12] The only systematic presentation of the issue from this angle known to the present writer is: H. Mannstaedt, *Die Kapitalistische Anwendung der Maschinerie* (1905). As "theory of compensation," the argument appears in many German textbooks. Cf. *e.g.*, Ad. Weber, *Allgemeine Volkswirtschaftslehre* (1928), p. 169.

equal to the number of his variables, . . ." (Letter to Colson, printed in *Econometrica,* Vol. I, 1933, p. 221). Evidently, in order to determine, on the basis of the wage fund the number of employed, one has to know the wage rate in terms of wage goods. On the other hand, in classical teachings, the wage rate itself is governed by the wage fund; it is obtained by dividing the wage fund by the number of employed: *one* equation, *two* unknowns! With the concept of a given stock of wage goods, it is consistent to conclude *either* that the laborers displaced in A are re-employed and the wage level remains the same, *or* that they are *not* re-employed, thus consuming less, while the real wage level of the still employed rises. The latter alternative, surprising as it seems at the first glance, is by no means improbable; we have only to remember that what is fixed contractually between employer and worker is not the real wage but the money wage rate; if the wage bill declines because of technological unemployment in some industry, the given stock of wage goods can be sold only at lower prices, as it usually happens at the beginning of a depression. If this alternative is accepted, it is tempting to deduce from this starting point a theory of depression; for, certainly, the producers of wage goods (whose costs have not yet declined!) would respond to lower prices with a short-run reduction of output; thus a chain of cumulative shrinkages could be supposed to be generated. However, this line of reasoning would imply the acceptance of a fundamental but faulty premise of the wage-fund approach, namely, that wage goods are rigidly separated from other consumer goods. There is not only a stock of wage goods in *process,* from which the continuous flow of wage goods emanates, but also stocks of "profit goods" in process, "rent goods" in process, etc., from which the flow of real income to the other classes is continually generated. Now even in the short run some transfer from the flow of wage goods to the other flows is possible; if the decline in the wage bill happened to be associated with a rise in profits, the wage fund would decline and the "profit fund" would rise. It follows that the classical equation: Wage Fund = Wage Rate (per period of gestation) times Employment, has *three* unknowns.[13] And such a rise of profits, parallel to the decline in the wage bill in A because of displacement of labor, is by no means restricted to cases of imperfect competition, as Douglas and Director, arguing in terms of average costs, supposed; whether, under perfect competition, profits or losses are created in the short run by the introduction of the new technical methods depends *inter alia* on the way in which the shape of the marginal cost curve is affected by the technological progress.

[13] Senior was not without misgivings in this respect. The ratio of wage goods produced to profit goods produced is, in his theory, governed by the profit rate (*op. cit.,* p. 174); the logical circle is complete.

It is not surprising that the analysis of the wage-fund theory of employment, on the whole, gave negative results. For this approach, as embodied in the equation above, is purely algebraic and does not indicate the causal mechanism, neither the motives of entrepreneurs nor the technical possibilities of re-employment. The classical theory had recognized that production is conditioned by the coöperation of fixed capital, circulating capital and labor, the ratio of capital to labor being governed by what later was called "the nature of industry," *i.e.*, the state of the arts; if so, how could the mere preservation of *circulating* capital ensure re-employment? Ricardo did not bother much about this question, because his "long-run" equilibrium concept was different from the later, neo-classical one,[14] denoting not equilibrium as worked out for a *given* quantity of factors available, but rather the terminating point of a process in which the rise or fall of the supply of labor and the changes in the current rate of capital accumulation adjusted both prices and factor remuneration to their "natural" level, and secured full employment of labor. The most logical conclusion (which was, indeed, drawn by Marx) would be to have current employment governed by the quantity of fixed capital available and the nature of the respective industry; then, technological progress that raises the amount of fixed capital necessary per worker would bring about displacement, to be compensated solely by further accumulation and investment of capital.

Later classical economists like Cairnes and Sidgwick,[15] being aware of these logical consequences of the Ricardian approach, tried to save the optimistic results of McCulloch and Senior in part by pointing out that additional fixed capital could also be provided by converting into fixed capital the working capital set free by the displacement of laborers. The quantitative significance of this process clearly would be small. Some theoretical comments on this suggestion may also be permitted here, because they will definitely clarify the position of working capital in the process of displacement and reabsorption. The setting free of working capital refers to the industry A where the technological progress materializes, not to the industries producing wage goods; because if these would reduce output and working capital, they would create *additional* unemployment, which would require an *additional* process of absorption.

Now, the output in industry A is certainly larger after the introduction of the new methods than before; otherwise, the price would not fall. Consequently, the *physical volume* of working capital in A must be *larger* than before, except in the case that the period of gestation is

[14] See F. H. Knight, *Risk, Uncertainty and Profit* (New edition, 1929), p. 143, footnote.

[15] J. E. Cairnes, *Some Leading Principles of Political Economy Newly Expounded,* (1894), pp. 190 *ff.*; H. Sidgwick, *Principles of Political Economy* (1883), p. 320.

reduced by the technological progress, which would imply a capital-saving device rather than a labor-saving one. Still it would be possible that the *value* of the stock of working capital is smaller than before, despite the larger quantity, because goods are now produced by less labor per unit of output. But even if the value happened to shrink, this would not imply an abundance of working capital which could be converted into fixed capital. Entrepreneurs in A would pay out, during the period of gestation, a smaller amount of funds to factors of production than they had before; in the subsequent period, the effective demand for commodities and the net amount by which the demand for goods in B, C, etc., is augmented, would be correspondingly smaller. In these industries, the entrepreneurs would respond to a lesser degree than assumed in Section I, by expanding output and working capital in the short run: any mobilization of the abundant working capital in A would, therefore, at the best, raise the compensation of the technological unemployment to the level indicated in our former analysis and no additional absorption would ensue.

Clearly, if, in the process of technological progress the flow of purchasing power is maintained, as the Law of Markets School assumes, then the aggregate value of working capital in the economic system would not shrink; its wage component may decline, but, because of rising prices or of a higher ratio of capital to labor (in B, C, etc.), the other components, *viz.*, profits and business payments, would rise.

V. Changes in the Wage Level and in the Quality of Equipment

Removing now, step by step, the strict conditions of the short run, we drop first the condition of an unchanged wage level. Technological unemployment could lower the wage level throughout the system. In the short run, where equipment is given as to quantity and quality, this would cause a downward shift of the marginal cost curve and would increase current output and capital, for any given state of demand. At the same time, a *long-run* process is started, adjusting the *quality* of equipment. Lowering the wage rate tends to bring about a combination of the given quantity of equipment with a *larger amount* of labor, implying the reabsorption of a certain number of displaced workers.

As pointed out in the beginning, this theory of compensation, being the offspring of modern equilibrium theory, has a greater theoretical validity than the two older approaches discussed in the preceding sections. Equally great is the difference between the scope of the compensation argument of the equilibrium school on the one hand and the two older approaches on the other hand. The Law of Markets School and the Wage Fund School tried, above all, to prove that the wage level would *not* be affected; the mechanism of absorption we are going to

discuss now does not support in any respect the older doctrines. Moreover, the practical significance of the equilibrium theory approach is small in the present era of relations between capital and labor, where wage rates have proved very inelastic in face of the pressure of unemployment.

We do not want, however, to dismiss the problem with such purely practical considerations. Too easily would it be argued that unemployment caused by technological process is not genuine, but would vanish in time if a sufficient wage reduction set into motion the mechanisms now under consideration. Theoretical comments on the neo-classical approach are the more in order, since the opinion seems to be commonly held (although never explicitly stated) that wage reductions, in order to be sufficient for reabsorption, need not be considerable, or would at least not reduce the worker's standard of living beyond a fair minimum.

As to the short-run effects of a wage reduction, our comments can be brief: (1) It is still an unsettled question of economic theory whether the assumption of an unchanged state of demand is compatible with the general decline in the wage level; (2) the degree of reabsorption of displaced workers, consequent to the reduction of wages, is, in the short run, theoretically not related, to the magnitude of displacement.[16]

More complicated is the theoretical analysis of the changes in the *quality* of equipment caused by a wage reduction. For it is precisely by these changes that, according to the neo-classical theory, a state of general long-run equilibrium is brought about; and in such a state, no unemployment in the *theoretical sense* could exist. A closer analysis of the mechanisms involved is necessary.

The term "change in the quality of equipment" covers two processes. The first is a consequence of the change in the *price relations* brought about by the decline in wage rates which sharply lowers the prices of all goods in the production of which relatively much labor and little capital is applied; consumers' demand will turn to these goods, and productive resources will be transferred to such "little capitalistic industries" (as they may be called from now), from highly capitalistic industries, increasing the amount of labor combined with an equipment of given *quantity*. The second process refers to the change in the methods of production within the specific industry; it is a process underlying the traditional marginal productivity analysis, where, with a given quantity of "capital," different quantities of labor are combined. Both

[16] Further results may be reached by a short-run *general* equilibrium analysis of a system of simultaneous equations, with equipment but *not* the wage level being given. Such a system has been developed recently by J. R. Hicks in *Value and Capital* (1938). The present writer has not yet been able to make it fruitful for the particular problems of this paper.

mechanisms together are supposed, in modern theory, to bring about general equilibrium in the long run.

The limits of the first mechanism are fairly clear. Obviously it would not work if in all industries the factors of production would be combined in the *same* fixed ratio. As illustration, let us assume that three units of labor are always combined with two units of capital. If, then, an equal amount of labor and capital is available, plainly one-third of labor would be unemployed all the time. On the other hand, if there are "industries," like the "industry" of personal services, in which labor needs not the combination with capital to operate, then it is certain that at a zero wage rate all labor would be employed. If this unrealistic assumption is discarded, however, the picture changes: at a positive wage rate, the equilibrium price for any good produced must be above zero, and then the demand for the product of the little capitalistic industry may not prove sufficiently elastic.

This possibility is somewhat concealed by the mathematical form in which the equilibrium theory is stated. Equilibrium is characterized by a system of equations, in which prices and output of the different goods and the different productive services are the unknowns; since the number of equations can be shown to equal the number of unknowns, there always seems to exist a set of solutions indicating the prices of goods produced and of productive services at which the latter are utilized in full and no longer unemployed in the theoretical sense, *whatever the volume of their supply.* However, these solutions need not give positive values for prices and output (not even real ones!); and if not, then they are meaningless, and no equilibrium exists on the basis of the data. In the following illustration, we use the original Walras model reproduced, in simplified form, by Cassel in his *Theory of Social Economy,* Book I, in which the methods of production, stated as "coefficients of production," are taken as fixed, because we wish to isolate the effects of the first mechanism from the second one, *viz.,* the marginal productivity mechanism. We assume

1. Two kinds of productive services with unknown prices z_1 and z_2
2. Two kinds of produced commodities with unknown prices p_1 and p_2
3. Demand elasticities equal to unity, depending only upon the price of the good in demand, *i.e.,* consumers' outlay being constant.

We denote by

S_1, S_2 the unknown output of the good produced,

D_1, D_2 the demand for these goods as function of their price

R_1, R_2 the available supply of productive services (say, of *labor* and *capital*)

$a_{1,1}$, $a_{1,2}$ the (known) amount of productive service 1 necessary to produce one unit of commodity 1 and 2, respectively,

$a_{2,1}$, $a_{2,2}$ the corresponding amount of productive service 2. We arbitrarily put the constant outlay for commodity 1 equal to that for 2, each equal to 10, the a-coefficients equal to 1, 2, 6, 4, respectively, and $R_1 = 1$, $R_2 = 10$. We have the following equations:

Price equals average costs: $a_{1,1}z_1 + a_{2,1}z_2 = 1z_1 + 6z_1 = p_1$

$a_{1,2}z_1 + a_{2,2}z_2 = 2z_1 + 4z_2 = p_2$

Supply equals demand: $S_1 = D_1 = 10/p_1$

$S_2 = D_2 = 10/p_2$

Full use of productive services: $R_1 = 1 = a_{1,1}S_1 + a_{1,2}S_2 = 10/p_1 + 20/p_2$

$R_2 = 10 = a_{2,1}S_1 + a_{2,2}S_2 = 60/p_1 + 40/p_2$

Solutions: $p_1 = 5$; $p_2 = -20$; $z_1 = -35/2$; $z_2 = 15/4$

As pointed out before, the negative prices for product 2 and productive service 1 are meaningless;[17] there is no full employment of all factors of production, on the basis of the data.

No specific illustration can be given which would show that an equilibrium system of equations in which the coefficients of production are variable, need not possess meaningful solutions either. The lack of reliable empirical material prevents a precise determination of the limits of the second mechanism. However, general observation renders it very likely that such limits exist, and that we are not entitled to expect from the marginal productivity mechanism the absorption of displaced workers beyond a certain, probably narrow limit. The present writer hazards the guess that in industry proper, as contrasted to agriculture and mining, the marginal productivity is very inelastic over the range beyond the combination of capital and labor which was obtained after the World War. To realize this more clearly, we only have to visualize a modern industrial enterprise like a steel plant, fully utilized in the short run, and to ask in what way and to what degree the plant, without increasing the quantity of equipment, could employ more labor if the wage level were lower. Certainly, a number of minor changes in the quality of equipment are possible which would permit employing more labor (say, for cleaning purposes); furthermore, by the removal of some gadgets of minor importance, capital might be set free, which, if added together for all steel plants, allows the establishment of a new steel plant that would absorb labor. However, to the present writer, it seems very doubtful that the total increase in employment caused by such methods could be of larger order of magnitude than a small percentage of the original volume of employment.

[17] The emergence of both, a negative price of the productive service and a negative price of the good produced, is accidental. We could construct cases in which a negative price of the service arises despite of all prices of goods being positive.

Marginal productivity theorists, however, sometimes envisage another type of technical change. The era in which the puddling process was replaced by the Bessemer converter and by the open hearth process (processes requiring a much higher amount of capital per worker than used before) was also the era of rising wage rates. Would not a sufficient lowering of wage rates revert the development and bring about the application of older processes requiring much less capital per worker? This argument overlooks that, even at a considerably lower wage rate, the puddling process may be less profitable than the open hearth process. In other words, the transition from one process to another is not correctly described by moving along a given marginal productivity curve for capital; a shift in the curves was caused by technological progress.

The detailed investigation of the elasticity of marginal productivity curves and the classification of industries according to this elasticity is one of the most important tasks of an empirically founded theory of employment. It must be repeated that it is pure guesswork to assume, as the present writer does, that highly capitalistic industries have a smaller elasticity than the little capitalistic industries, particularly agriculture and mining. However, there is also a theoretical argument showing that under the conditions of modern industry the marginal productivity mechanism needs not always secure general long-run equilibrium. If to the Walras equation system, described above, a new set of equations is added, indicating the choice of methods of production as contingent upon the prices of productive services, then some of the obstacles are removed that may prevent meaningful solutions to materialize for the price and output magnitudes. But, by such an introduction of *variable* coefficients of production, a new difficulty is added at the same time.[18] The marginal productivity mechanism can be considered to solve, theoretically, the unemployment problem in the long run only if equilibrium can be obtained *for any possible combination of capital and labor.* But it is a well-known mathematical fact that this is the case only if economics of large scale are completely absent (or, to express it in a more sophisticated way, if the production function is homogeneous of the first degree); then, and only then, the sum of factor remunerations according to their marginal productivity would just equal the market value of output, creating neither profit nor loss to the entrepreneur, whatever the combination of labor and capital. If, on the other hand, economics of the large scale are present, general

[18] We cannot discuss here the complicated but most realistic case in which fixed and variable coefficients appear in the production of one and the same good. Neither can we analyze the peculiar instance of variability in which the ratio of productive services employed is always the same, however large the output of the firm, although the absolute amount of input per unit of output declines with rising output.

long-run equilibrium is still possible, but only for *specific* combinations of labor and capital. The implications of this theoretical proportion are not yet fully explored. One thing is certain, however; the marginal productivity mechanism, currently at work in absorbing labor if wage rates decline, may fail, by itself, to secure general long-run equilibrium, and to eliminate permanent unemployment in the neo-classical sense.

The present writer is quite far from denying that the two mechanisms discussed in the preceding paragraphs are significant in absorbing unemployment. However, in a stationary state, with equipment given as to quantity they will work only very slowly. Even if wage rates declined, it would take a long time before an entrepreneur starts moving the immobilized resources from one industry to another, and further time till the process is completed; likewise, a change in the methods of production under the influence of lower wage rates is slowly started and slowly executed. It is only in a progressive state that the two mechanisms obtain a greater weight by directing investment into channels in which the new equipment will employ more workers per unit than if the wage level has not declined. However, to the largest extent, it is the expansion of the economy *itself, i.e.,* the changes in the *quantity* of equipment, that all the time has absorbed displaced labor. Before commenting on this process, however, we must take time out to revise the tentative definition of the labor-saving device given in Section II.

VI. A Working Concept of Labor-Saving Inventions. Demand Elasticities Equal to and Larger than Unity

The introduction of the marginal productivity concept permits us to formulate a less objectionable definition of the labor-saving device; at the same time we shall be enabled to ascertain how far the results of the first section, obtained for a demand elasticity smaller than unity in industry A, are applicable to demand elasticities equal to and larger than unity. We describe, in the usual fashion, the production process in industry A by a marginal productivity function, here for labor (product measured in terms of current prices); the area below the curve indicates the volume of output, produced by coöperation of a given volume of other factors (here "capital") and a varying amount of labor (OL); the wage rate is considered equal to the marginal product of labor ML.

The technological progress in question would be indicated by a shift in the function, which at least partly would be upwards, and must satisfy the condition that the current output can be produced now with a smaller amount of labor OL_1 (*i.e.,* $OPML = OP_1M_1L_1$). Now if the progress is of the type indicated in Figure 1 (where the marginal productivity of labor is raised, for any amount of labor $< L$), then entrepreneurs will not be satisfied with producing the same output as before

Increase in the labor force is impossible under the second type[19] of technological progress depicted in Figure 2, where $OP_1M_1L_1$ again equals OPML, but where the new curve lies partly below the old one, to the left of L. Even under an infinitely elastic demand, it would be impossible to increase output to such an extent that no displacement occurs, unless, of course, the wage level declines. Since such a decline is usually not foreseen, the entrepreneurial plans would refer to employment OL′ and leave some amount of workers to be absorbed in B, C, etc., either, in the short run, by better utilization, or, in the long run, by an adjustment of the equipment.

We find, therefore, three alternative definitions of labor-saving devices installed in an individual industry. The widest one would include inventions that (1) reduce the amount of labor necessary to produce the current volume of output, *and* (2) cause, at the current wage level, a displacement of labor in the industry concerned, because of a small elasticity of *either* the new marginal productivity curve *or* of the demand for the goods produced; this definition would cover also type (1) above (Figure 1). A somewhat narrower definition would cover only such devices which, besides satisfying condition (1) above, cause a displacement because of the low elasticity of the marginal productivity function, *regardless* of the demand elasticity; this definition corresponds to type (2) above. The narrowest definition would include only devices which also would cause a displacement if the *current* wage rate is replaced by a *minimum* rate, fixed from the viewpoint of social justice.

If the present writer's conjecture is correct that, in industry proper, the marginal productivity of labor (in the long-run sense) tends to become less and less elastic the more capital is employed per worker, then the difference between the second and the third definition would be small, because even a substantial reduction of wage rates in A would not increase employment to a considerable extent. On the other hand, the difference between the first and second definition is very likely of great practical importance. Many devices which would not prove labor-saving if the market price of the commodity remained unchanged will become so on account of a low demand elasticity. Labor-saving inventions according to the first definition are, therefore, frequent, and only the compensatory effects of changes in the quality and especially in the *quantity* of equipment have prevented net technological unemployment from taking vast dimensions.

The present approach to a working definition of labor-saving inventions differs from the definition as elaborated, on the basis of Professor Pigou's work, by Professor Hicks.[20] Hicks calls an invention labor-

[19] We disregard here the further type in which, at the given wage level, it is most profitable to produce less than before.

[20] J. R. Hicks, *Theory of Wages* (1932), pp. 122 *ff*.

saving if the relation of the actual marginal productivity of labor to that of capital is lowered. He considers, therefore, the effect of the invention on the position of labor in the *whole economy,* assuming that the long-run adjustment of the quality of equipment is realized throughout, and that the ensuing changes in the price relations of commodities are insignificant; the question whether an invention creates unemployment, cannot arise, since all short-run unemployment is supposed to be reabsorbed. The exact relation of Hicks's definition to ours is complicated and cannot be discussed here for lack of space.

VII. Changes in the Quantity of Equipment

In actual fact, the reabsorption of displaced labor has been brought about, to by far the largest extent, by the accumulation and investment of capital; much more, indeed, than by the processes analyzed in the preceding sections. It never has been doubted by any theorist of rank that accumulation of capital in the form of fixed equipment raises the demand for labor; Marx especially,[21] consistently expounding the paramount ideas of the Ricardian system, depicts the capitalistic process as a race between displacement of labor through technological progress and reabsorption of labor through accumulation. The same view has been expounded with great clarity by a modern "marginalist" economist, L. V. Birck.[22] Quite naturally, this approach has not been considered satisfactory by the "harmonistic" economists of the Law of Markets School or Wage Fund School; displacement and accumulation are two largely *independent* factors, and it is impossible to predict the outcome of the race between the two on purely theoretical grounds. Marx believed, mainly on the basis of the experience of the twenties and thirties of the last century, that displacement more and more would outweigh accumulation, but the experience of the fifty years after the publication of the first volume of *Kapital* refuted his forecast. On the other hand, the experience of the last twenty years is less favorable, at least more controversial.

This side of the question need not be followed up in this paper. More important is a theoretical qualification. Without doubt the two contestants of the race are not *entirely* independent. A rise in aggregate income, generated by technological progress, would increase also the rate of accumulation (per time unit), and thus speed up the reabsorption of labor. However, the proposition that "permanent" technological unemployment is impossible does not find much encouragement in this

[21] K. Marx, *Kapital,* vol. I, chap. 23. In popular literature (and sometimes even in scientific writings), capital accumulation and technological progress are frequently confused, and Marx is credited with an opinion opposite to that which he really held.

[22] "Theories of Overproduction," *Econ. Jour.,* vol. 37, pp. 19-32.

fact. First of all, the favorable effect on accumulation can only materialize if a "moving equilibrium" is preserved in the economy; if, contrariwise, displacement of labor (in the absence of compensatory investment) by reducing consumers' purchasing power ushers in a depression, the favorable effects on accumulation of displacement might not materialize. Even more important is another reflection: the amount of capital needed per worker according to the "nature of the industry" is a timeless magnitude, in the sense that, though changing over time, it exists at any moment. Accumulation of capital, on the other hand, is a magnitude that possesses the dimension of time: so much *per week*, for example. The two magnitudes cannot be directly compared; the correct way of relating them is: it would take, at the old rate of accumulation, so many years of one man's wages to accumulate enough capital to re-employ one man; and at the new, presumably higher rate, this many years. Now what is important in this context is that the same process that reduces the number of years, by speeding up the rate of accumulation, also *increases* this number by enhancing the amount of capital per worker. Thus, even under favorable conditions (continuous prosperity), the rate of labor absorption through accumulation remains rather unaffected by the technological progress, and still can be considered as a largely independent variable.

The conclusion is inevitable: there is no mechanism within the framework of rational economic analysis that, in any situation, would secure the full absorption of displaced workers and render "permanent" technological unemployment in any sense impossible. How long the unemployment will last can be answered only by "economic biology," which, in an all-embracing economic-sociological approach, tries to evaluate the strength of all forces working in the society.

TAX SHIFTING IN THE MARKET PERIOD

By ELMER D. FAGAN

In the analyses of tax shifting, economists have concerned themselves primarily with the long-run period. Few of them have given attention to the short-run period; and none of them has studied the probable effect of taxes on prices in the market period.[1] The present article is concerned, therefore, with an analysis of the effect of taxation on the disposition and price of goods already on hand, under conditions of both pure and monopolistic competition.[2] In this analysis, it will be shown that taxes which affect the disposition of stock-on-hand also affect simultaneously the rate of output in the succeeding production period. In other words, it will be shown that the seller's market period plans and short-period plans are synchronized.[3] It is the reality of this synchronization which has dictated the substitution of a sequence analysis for the Marshallian static analysis in the present study.

In Part I of this analysis, it is assumed that sellers have on hand a highly perishable product for which there is neither the possibility of carry-over nor of self-use. In Part II, it is assumed that carry-over and self-use are possible. The two parts of the study are not, however, of coördinate importance. The problems considered in Part II certainly

[1] Throughout this study, market price refers to a price which is determined in the market period, *i.e., a* period in which the supply of a good cannot exceed the stock already produced and on hand.

[2] The reasoning and conclusions in this article are based upon the following general assumptions for both pure and monopolistic competition: (1) that taxes are general, (2) that taxes are viewed as permanent by taxpayers, (3) that taxes do not affect demand schedules, and (4) that "pure competitors" have identical cost and demand curves; and that monopolistic competitors also have identical cost and demand curves. The definitions of pure and monopolistic competition which have been adopted in this article are those which have been given by Professor Chamberlin in *The Theory of Monopolistic Competition,* 3rd ed., pp. 7-9. The analysis of the effect of taxation on price under monopolistic competition involves the following additional assumptions: (1) that there is complete price interdependence between sellers, and (2) that the effects of selling costs, the total of which is assumed to be constant, are represented in the demand curve for the product of each firm. Under these assumptions, any one firm may be regarded as a representative member for the group.

[3] In the present study, it is assumed that a producer's plans do not extend beyond the market period and the succeeding production period. The length of this succeeding period is assumed to be typical of the production of a particular commodity, with existing scale of plant. It is such a "succeeding period" which is called the "short-run period" in the present article.

correspond more closely to those encountered under actual conditions than do the problems considered in Part I. They also call for more elaborate analysis. Hence the major attention will be devoted to Part II.

The forms of taxation which are considered are those which, in the writer's opinion, are most likely to be imposed or increased in democratic states, *viz.*, specific sales tax, *ad valorem* sales tax, lump-sum tax, and net returns tax.[4]

I. Carry-Over Impossible

To the readers to whom this article is addressed, no argument is needed in support of the generalization that under conditions of pure competition and no reservation prices, price in the market period will not be affected by the imposition of any of the following forms of taxation: specific sales tax, *ad valorem* sales tax, lump-sum tax, net returns tax.

It is also clear that under conditions of monopolistic competition and no possibility of carry-over or of self-use, price in the market period will not be affected by either a lump-sum or a net returns tax. The effect on market price of a specific and an *ad valorem* tax under conditions of monopolistic competition requires, however, a brief explanation. The analysis is facilitated by the use of a diagram.

In Figure 1, volume of sales is measured along OX and price per unit along OY. For the volume of sales OH, marginal revenue is equal to

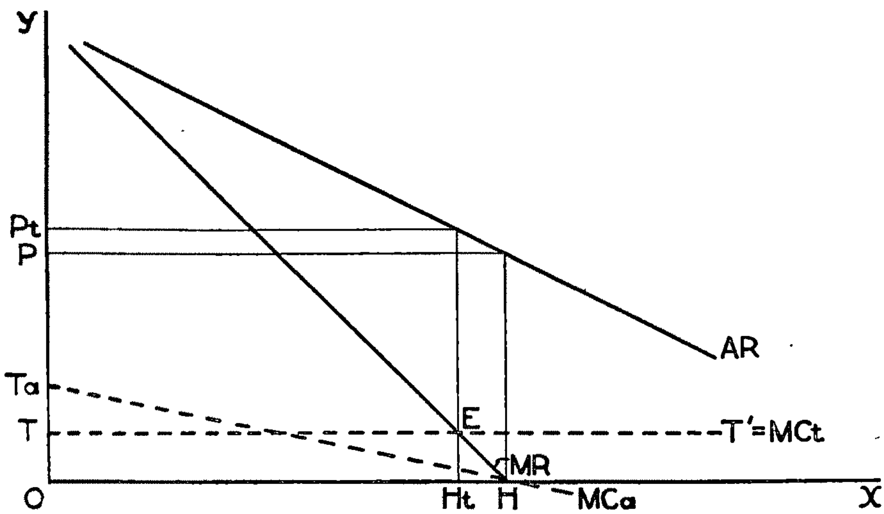

FIG. 1

[4] The effect of a gross receipts tax of a given percentage is, of course, identical with that produced by an *ad valorem* tax of the same percentage.

zero. Since cost of production, exclusive of tax, is "ancient history" in the market period, profits are maximized or losses minimized when marginal revenue is equal to zero. Therefore, the most profitable pre-tax volume of sales is OH. For this volume of sales, price is OP = $10.00. If a specific sales tax of $2.00, OT, is imposed, the marginal cost of the privilege of selling = TT′ or MCt. Marginal cost intersects marginal revenue at point E. This point of intersection establishes the most profitable post-tax volume of sales OHt. The decrease in the volume of sales from OH to OHt causes price to increase from OP to OPt.

If an *ad valorem* tax of 20 per cent had been imposed instead of the specific tax, the pre-tax marginal cost, *viz.*, zero, would have been increased for each several volume of sales by an amount equal to the product of the marginal revenue for each several volume of sales times the rate of the *ad valorem* tax. The imposition of an *ad valorem* tax would give the marginal cost curve TaMCa. This marginal cost curve intersects the marginal revenue curve at point H. The most profitable post-tax volume of sales is, therefore, identical with the most profitable pre-tax volume. Since the volume of sales is unchanged, market price is not affected. The tax is not shifted.

From the preceding analysis the conclusion is the following: Under conditions of monopolistic competition and no carry-over, a specific sales tax will, but an *ad valorem* tax will not, cause an increase in price in the market period.

II. Carry-Over Possible

A. Specific Sales Tax

1. *Pure Competition*

It is a familiar fact that under both pure and monopolistic competition the individual seller is in market equilibrium when his reservation price is equal to marginal revenue. Under pure competition, marginal revenue is equal to a price which is determined by the market equilibrium of demand and supply for the *industry*. The seller's curve of reservation prices is his market supply curve.

Variations in the volume of carry-over by the individual seller do not affect appreciably the marginal cost of storage, the relevant rate of interest, or the future price of the product. Since this is true, the seller might be expected, at first blush, to have only one reservation price for his total stock, *viz.*, a price equal to expected future price minus carrying costs. This would not be the case, however, if the seller faced either of the following conditions: (1) if he desired to retain a portion of his product for his own use, *e.g.*, a portion of his grain for seed; or

(2) if he made allowance for the increase in marginal risk aversion involved in an increase in the volume of his carry-over.[5]

In real markets sellers are usually affected by one or both of these conditions. It is clear that the presence of either or both of these conditions would produce for the individual seller a schedule of reservation prices rather than a single reservation price for his whole stock.[6] Such a schedule when represented graphically would result in a positively inclined market supply curve. The market supply schedule for the industry would be the sum of the amounts offered at each several price by all the sellers in the market. This schedule would also produce a positively inclined market supply curve for the industry. Price would be determined by the market equilibrium of demand and supply for the industry.

The individual seller will regard a specific sales tax as a deduction of an equal amount from the price of his product. Since the deduction would be identical in either the present or future market, it follows (1) that the tax would not alter the balance of economic attractiveness between the present and future market; (2) that it would not affect either the volume of sales or the price in the market period; and (3) that the tax would not be shifted. These generalizations must, however, be modified to allow for the influence of two factors. First, other things equal, sellers would probably prefer to wait and pay their specific taxes on future sales rather than to pay them in the present on present sales.[7] This preference for deferred taxation would, of course, cause a decrease in the volume of sales in the present market and would cause an increase in market price. The magnitude of the price increase would

[5] This risk refers to the risk incident to market fluctuations as distinct from such insurable risks as fire, flood, etc. The costs of the latter are, of course, included in the carrying costs. The term "risk allowance" when used in the following pages refers to the allowance for the former type of risk. The importance of this factor was suggested to me by my colleague Professor Edward S. Shaw who has shown the importance of the risk factor in his stimulating study: "The Elements of a Theory of Inventory," *Jour. of Pol. Econ.*, vol. xlviii, pp. 465-85.

[6] The fact that the presence of condition (1) would give an upward slope to the market supply curve calls for no explanation. The risk factor will also tend to give an upward slope to the supply curve. Since the seller is not certain that he will receive the "expected future price" for his product, it is clear that the greater the volume of carry-over, the greater the financial risk involved, relative to his total economic position. This increase in the proportion of his total resources subjected to risk would cause an increase in marginal risk aversion. Because of this increase in marginal risk aversion the seller might be willing to sell a portion of his stock at a price equal to the difference between (a) a price somewhat lower than the expected future price and (b) carrying costs. This would, of course, give an upward slope to the market supply curve.

[7] Hereafter, this preference for deferred taxation will be referred to as tax discount. The preference for present over future revenue from sales is a factor which played its part in the determination of the *pre-tax* balance of economic attractiveness and of the *pre-tax* allocation of sales between the present and the future market.

depend upon (1) the rate of the tax, (2) the relevant discount rate, (3) the length of the period of time between the present and future market, and (4) the elasticity of the market demand for the product. Second, the tax might also upset the balance of economic attractiveness between the present and future market, in favor of the latter, by causing expected future price minus carrying costs *and tax* to become greater relative to present price *minus tax* than was the expected future price minus carrying costs relative to present price. This factor, like the first, would cause an increase in market price.

2. *Monopolistic Competition*

No argument is needed here in support of the generalization that either a monopolist or a monopolistic competitor who is selling in two markets which are completely separated spatially, so far as buyers are concerned, will maximize his profits by producing an amount at which marginal cost of production for the entire amount sold in both markets is equal to "aggregate marginal revnue." The portion of the total output which will be allocated to each of the two markets will be an amount such that marginal revnue in the two markets will be equalized.[8]

These generalizations are also valid in the case of either a monopolist or a monopolistic competitor who is selling in two markets which are completely separated temporally. Let us assume that a monopolistic competitor has decided upon the most profitable disposition of his present stock between the present and future markets. In reaching this decision he must have considered the nature of both the marginal revenue and the marginal cost curves in the future market. In other words, his decisions concerning the volume of sales in the market period and in the short-run period must have been made simultaneously.[9]

The effect of the imposition of a specific sales tax on the seller's decisions and, consequently, upon market price can be shown most clearly by the use of a diagram.[10]

[8] For the argument in support of these generalizations, see Joan Robinson, *Economics of Imperfect Competition,* 1934, pp. 181-85. There Mrs. Robinson explains the nature of "the aggregate marginal revenue curve" which she employs. The present writer has adopted Mrs. Robinson's terminology.

[9] In this article, it is assumed that the expected future price from which the seller subtracts carrying costs and risk allowance in order to establish reservation price is the short-run price, *i.e.,* price determined in the short-run period when the short-run period is defined as in footnote 3.

[10] In what follows it is assumed that prices and marginal revenue are expected to be higher in market II than in market I. If, however, it were assumed that prices in the future market were expected to be lower than prices in the present market, the producer could not, of course, equalize marginal revenue in the present and future markets in cases where the attainment of this objective would involve the transfer of goods from the future to the present market. In such a case the producer's volume of sales in the present and future markets would be such that the difference between the marginal revenue in the two markets would be reduced to a minimum. This would be achieved, in such a

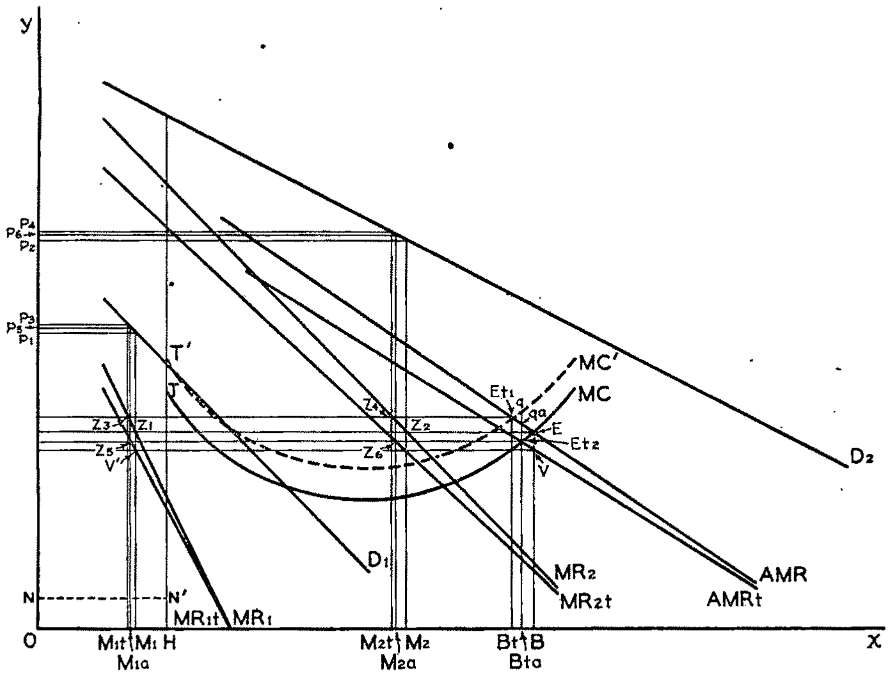

FIG. 2

In Figure 2, OX = output; OY = price; OH = stock-on-hand; OB = the sum of the volume of sales in both the present and future markets; D_1 = the demand curve or average revenue curve in the present market (market I); MR_1 = marginal revenue in market I; D_2 = the expected demand curve or expected average revenue curve in the future market (market II); MR_2 = marginal revenue in market II; AMR = aggregate marginal revenue in markets I and II, *i.e.* the sum of the abscissas of MR_1 and MR_2; and OHTMC = the marginal cost curve of the entire volume of goods offered for sale in both markets I and II. The marginal cost is, of course, zero for the stock-on-hand, OH. The marginal cost curve for the production in market II is TMC.

Marginal cost for the sum of the quantities sold in both markets I and II is equal to aggregate marginal revenue when the volume of sales in both markets is OB. The volume of sales in market I is OM_1. Marginal revenue at this volume in market I is M_1Z_1. Price in market I is OP_1. The volume of sales in market II is OM_2 or M_1B. Marginal revenue at this volume is M_2Z_2, and is equal to marginal revenue in market I. Price in market II is OP_2.

case, by selling total stock-on-hand in the present market and by producing and selling in the future market an amount at which short-run marginal cost would be equal to marginal revenue in the future market.

If a specific sales tax equal to TT′ is imposed, it will raise marginal cost at every point by the amount of the tax, giving the new marginal cost curve NN′T′MC′.[11] This new marginal cost curve intersects the aggregate marginal revenue curve AMR at E_{t1}. This point of intersection fixes the seller's new total volume of sales at OB_t. The volume of sales in market I becomes OM_{1t}, marginal revenue becomes $M_{1t}Z_3$, and price becomes OP_3. In market II, the volume of sales becomes OM_{2t} or $M_{1t}B_t$, marginal revenue becomes $M_{2t}Z_4$, and price becomes OP_4. Short-run price, *i.e.*, price in market II, is increased by an amount equal to P_2P_4. Market price, *i.e.*, price in market I, is increased by an amount equal to P_1P_3.

Figure 2 does not, however, give a completely accurate picture of the seller's volume of sales and prices in markets I and II, either before or after the imposition of the tax.

Before the imposition of the tax, a rational seller would have considered not only the marginal revenue in markets I and II but also (1) carrying costs, including interest, involved in holding goods from market I to market II, and (2) the increase in marginal risk allowance. These two factors would, of course, make for a larger volume of sales and a lower price in market I; and for a smaller volume of sales and a higher price in market II than the respective quantity and price magnitudes which are shown in Figure 2. The most profitable volume of sales in each of the two markets would be such that MR_1 would be equal to $MR_2—(CC + RA)$, when $CC =$ carrying cost, including interest, and $RA =$ risk factor.

After the imposition of the tax, the seller must consider an additional factor, *viz.*, the advantage of paying a specific sales tax in the future market rather than in the present market. In other words, the seller will discount a tax the payment of which can be made in the future. This new factor (TD), the desire to postpone the payment of a tax, will tend to decrease the volume of sales in market I and increase the volume of sales in market II. Its influence is directly opposite to that exercised by carrying costs and risk allowance. When all three factors are taken into consideration, the seller will maximize his profits or minimize losses by selling an amount in each of the two markets such that MR_1 will be equal to $MR_2 — (CC + RA — TD)$. If TD, tax discount, is less than $(CC + RA)$, the volume of sales in market I will be slightly greater than OM_{1t} and price will be slightly lower than OP_3. In market II, the volume of sales will be slightly less than OM_{2t} and price will be slightly higher than OP_4.

[11] The imposition of the specific tax TT′ would raise the marginal cost of *selling* any portion of OH in either market I or II by the amount of the tax. The marginal cost of selling any portion of OH would be raised from zero to ON, when ON = TT′.

B. AD VALOREM SALES TAX

1. *Pure Competition*

Other things equal, a seller will not hold a product for a future market unless he expects the future price to be higher than the present price by an amount sufficient to cover carrying costs and to offset risk allowance. The seller would see, therefore, that an *ad valorem* sales tax would be greater on the sale of a unit of product in the future market than on its sale in the present market. This fact would alter the balance of economic attractiveness between the present and the future market.[12] The seller would increase his sales in the present market (market I) and decrease his carry-over for the future market (market II) until price in market I, minus the tax, would be equal to expected price in market II, minus carrying costs, risk allowance, and the tax which would be assessed against the higher selling price.

The case can be explained most clearly by use of a diagram.

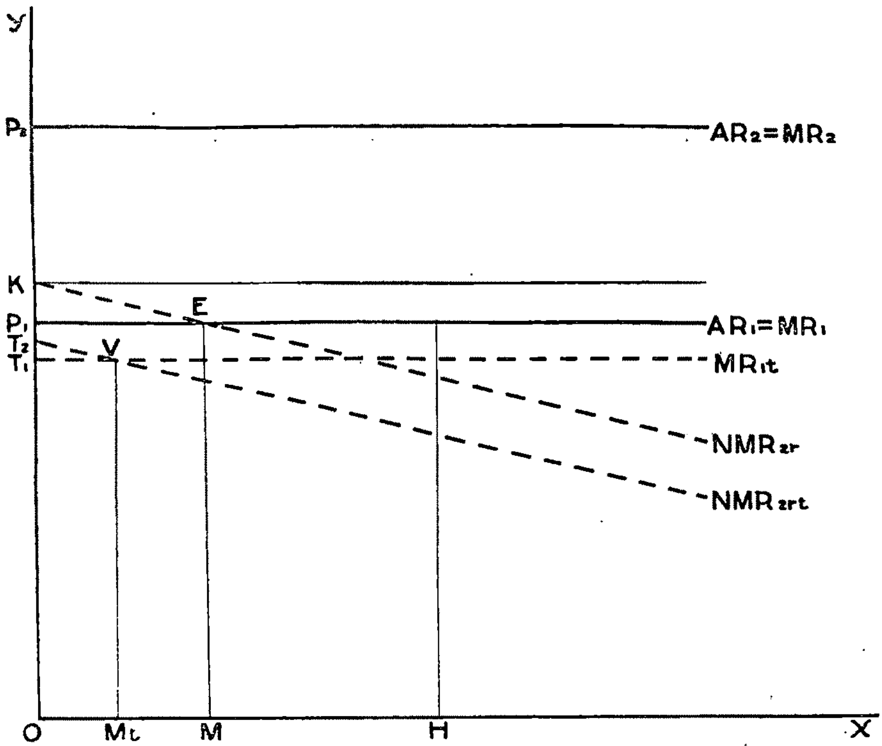

FIG. 3

[12] It is here assumed that the tax if paid on the sale of a unit of product in market II would be sufficiently greater than if paid on the sale of a unit of product in market I to more than offset the desire, other things equal, to postpone tax payment from market I to market II.

In Figure 3, OX = volume of sales; OY = price; OH = stock-on-hand; OP_1 = price in present market (market I); OP_2 = expected price in future market (market II); OK = expected future price minus carrying costs; NMR_{2r} = marginal revenue net of both carrying costs and risk allowance.

Before the imposition of the tax, the sales in market I = MH and carry-over for market II = OM. This distribution of stock-on-hand enables the seller to maximize profits or minimize losses. In market II, expected marginal revenue, net of carrying cost and risk allowance, is equal to marginal revenue and average revenue in market I.

After the imposition of an *ad valorem* tax of, say, 10 per cent, marginal revenue, net of tax of 10 per cent of $10.00, becomes OT_1 in market I. Marginal revenue, net of tax, *i.e.*, MR_{1t} is lower at every point than MR_1 by $1.00. In market II, the tax reduces NMR_{2r} at every point by an amount equal to 10 per cent of price in market II. Since price in market II is $15, NMR_{2r} is made lower at every point by $1.50. NMR_{2r}, net of tax, is represented by NMR_{2rt}. Marginal revenue, net of carrying costs, risk allowance, and tax, in market II is now equal to marginal revenue, net of tax, in market I when sales in market I are M_tH and carry-over for market II is OM_t. The tax causes the seller to decrease his carry-over for market II and to increase his sales in market I by an amount equal to M_tM.

Since the factors which affect the decisions of any individual seller are qualitatively representative of those which affect every other seller in the same market, there will be a reduction of carry-over for market II and an increase in sales in market I by all sellers of the product. Since the market demand for the product of the industry is negatively inclined, the increase in total sales of the industry in market I will cause market price to *fall*. The extent of the decrease in market price will depend upon (1) the magnitude of the increase in the total volume of sales in market I and (2) the elasticity of the market demand for the product of the industry. The seller will receive, net of tax, from the sale of each unit of product an amount equal to the new market price minus the tax.

A comparison of the effect on market price of a specific and an *ad valorem* tax shows that the former will cause an increase in market price. The latter, on the other hand, will cause a *decrease* in market price.

2. *Monopolistic Competition*

In the discussion of the effect on market price of a specific tax, under conditions of monopolistic competition it was shown how the seller must distribute the sales of his stock-on-hand between the present and

the future market in order to maximize profits or minimize losses.

Before the imposition of an *ad valorem* sales tax of, say, 10 per cent, the seller will maximize profits or minimize losses by selling his stock-on-hand, OH (Figure 2), by selling OM_1 in the present market (market I), and M_1H in the future market (market II). Production in market II will be HB. Total sales in both markets will be OB. Marginal revenue in market I will be M_1Z_1; and will be equal to marginal revenue in market II, M_2Z_2. Price in market I will be OP_1; and in market II, OP_2.

The imposition of an *ad valorem* sales tax will reduce the marginal revenue, net to seller, in both markets I and II and also the aggregate marginal revenue, net to seller, by a percentage equal to the rate of the tax. Under the assumption that the tax rate is 10 per cent, the marginal revenue curve, net of tax, in market I will be MR_{1t}; and in market II, MR_{2t}. The aggregate marginal revenue curve, net of tax, will be AMR_t.

The marginal cost curve for the total output in both markets, OHTMC, intersects AMR_t at point E_{t2}. This point of intersection fixes total sales at OB_{ta}. In market I, sales decrease from OM_1 to OM_{1a}. Marginal revenue, net of tax, becomes $M_{1a}Z_5$ and market price rises from OP_1 to OP_5. Carry-over for market II increases from M_1H to $M_{1a}H$. In market II, production falls from HB to HB_{ta} and sales decrease from OM_2 to OM_{2a}. Marginal revenue, net of tax, becomes $M_{2a}Z_6$ and price increases from OP_2 to OP_6.[13] The magnitude of the changes in price in the two markets is dependent upon (1) the rate of the tax, (2) the elasticity of the demand curves, (3) the slope of the marginal cost curve within the relevant range, and (4) the amount of stock-on-hand. If the marginal cost curve were absolutely inelastic within the relevant range, the volume of sales and price in market I would remain unchanged.[14]

It is now possible to compare the effect on market price of a specific and an *ad valorem* sales tax under conditions of monopolistic competi-

[13] Figure 2 does not indicate the influence of carrying costs, allowance for risk, nor the desire, other things equal, for the postponement of tax payment. The quantitative effect of the *ad valorem* tax on sales and prices as shown in Figure 2 are, therefore, not completely accurate. Complete accuracy can be achieved, however, by making the same modifications which were found necessary for the attainment of completely accurate results in connection with the diagrammatic analysis of the effect on market price of a specific sales tax under conditions of monopolistic competition. See above, p. 78.

[14] The reasoning in support of this generalization follows: If MC were absolutely inelastic it would lie along BE and would be cut by AMR_t at point V. Sales in markets I and II would be of amounts such that marginal revenue, net of tax, in these markets would be equal to BV. Since AMR_t is lower than AMR by 10 per cent at every point, EV is 10 per cent of BE. In other words, BV is less than BE by 10 per cent. Since BE and M_1Z_1 are equal, marginal revenue, net of tax, in market I must be 10 per cent lower than M_1Z_1. Marginal revenue, net of tax, in market I is exactly 10 per cent lower than M_1Z_1 at point V′. Since the abscissa of V′ is equal to OM_1 volume of sales and price in market I are unchanged.

tion.[15] It has been shown in an earlier section of this article that a specific sales tax causes a reduction in sales in market I and an increase in market price.[16] The specific tax will always cause these results under the following conditions: (1) a negatively inclined marginal revenue curve in market I, (2) a negatively inclined aggregate marginal revenue curve, (3) a positively inclined or an absolutely inelastic marginal cost curve within the relevant range, and (4) the intersection of MC′ and AMR at a point with an ordinate lower than the ordinate of the highest possible marginal revenue in market I.

An *ad valorem* sales tax also causes a decrease in sales in market I and an increase in market price unless the marginal cost curve is absolutely inelastic within the relevant range. In that case, the volume of sales in market I and market price are unchanged.

If at the time either a specific or an *ad valorem* sales tax is to be levied the specific tax is a percentage of market price which is equal to the rate of the *ad valorem* tax, the specific tax, under a wide range of conditions, will cause a greater decrease in sales and a greater increase in price than would have been effected by the imposition of the *ad valorem* tax.[17]

A comparison may now be made between the effect on market price

[15] For a comparison of the effect of a specific and an *ad valorem* sales tax on short-run price, see E. D. Fagan and R. W. Jastram, "Tax Shifting in the Short-Run," *Quart. Jour. of Econ.*, Aug., 1939, pp. 562-89. In this earlier article, unlike the present, the short-run period was treated entirely independently of the market period. The difference in the effect of the two forms of taxation on short-run price are, however, qualitatively the same in both cases.

[16] See above, pp. 76-78.

[17] The conditions under which the specific tax will cause the greater increase in price are the following: The aggregate marginal revenue for the equilibrium output which would be established following the imposition of the *ad valorem* tax must be less than the price per unit of the untaxed sales in market I. That is to say, $B_{ta}Q_a$ must be less than OP_1. The conditions under which the comparison between the effect on price of the two forms of taxation is being made are satisfied if it is assumed that market price, OP_1, in Figure 2 is \$20, that the specific tax is \$2.00, and that the rate of the *ad valorem* tax is 10 per cent. Under these conditions, $E_{t2}Q_a$ is 10 per cent of $B_{ta}Q_a$. Since $B_{ta}Q_a$ is less than OP_1, $E_{t2}Q_a$ is less than the amount of the specific tax $E_{t2}Q$ which is 10 per cent of OP_1. Now MC′ passes through point Q. Since MC′ slopes downward to the left of point Q, and since the negatively inclined aggregate marginal revenue curve, AMR, passes through point Q_a, MC′ cuts AMR at E_{t1}, a point which is to the left of points E_{t2} and B_{ta}. This point of intersection, E_{t1}, fixes the aggregate sales at OB_t. This volume of sales is less than OB_{ta}, the volume which would have resulted from the imposition of the *ad valorem* tax. Since the aggregate volume of sales is less under the specific tax, aggregate marginal revenue, including the tax, is greater. Since marginal revenue, including the tax, in markets I and II is always made equal to aggregate marginal revenue, including the tax, and since aggregate marginal revenue, including the tax, is greater after the imposition of the specific tax than it would have been under the *ad valorem* tax, it follows that the specific tax would cause a greater increase in marginal revenue, including the tax, in markets I and II than would the *ad valorem* tax. The greater marginal revenue in market I corresponds, of course, to a smaller volume of sales and a higher price. Therefore,

of a specific and an *ad valorem* sales tax under conditions of pure competition on the one hand and monopolistic competition on the other. Under monopolistic competition, it has just been shown that the specific tax, under a wide range of conditions will cause a greater increase in market price than would have been effected by the *ad valorem* tax. Under pure competition, a specific tax will cause an increase in market price. The *ad valorem* tax will cause a *decrease* in market price.[18]

C. LUMP-SUM SALES TAX

1. *Pure Competition*

Since the lump-sum tax is a tax of a fixed amount, the seller is not able to solve the problem of the most profitable post-tax distribution of his stock-on-hand between present and future markets on the basis of marginal adjustment. It is an all-or-nothing proposition. More specifically, the seller must sell nothing at all in market I in order to escape the payment of the lump-sum tax in the present market; and if he should sell all his stock-on-hand in the future market, there would be no *additional* taxes in that market.[19]

The seller's post-tax decision concerning the most profitable distribution of his stock-on-hand between markets I and II will depend upon the answer to the question: If total stock-on-hand were sold in market II, would probable receipts be sufficiently greater than receipts from the pre-tax allocation of sales of the same stock minus the lump-sum tax in market I, to more than offset additional carrying costs plus the money equivalent of additional risk aversion? If the answer to this question is Yes in the case of an appreciable number of sellers, the volume of sales in market I would decrease, and market price would increase.[20] If the answer is No in the case of all or of all except an inappreciable number of sellers, the most profitable post-tax volume of sales in market I would, of course, be identical or virtually identical with the most profitable pre-tax volume, and market price would be unchanged.

---

it may be concluded that the specific tax would cause a greater increase in market price than would the *ad valorem* tax.

[18] The comparison of the effect on market price of a specific and an *ad valorem* sales tax under conditions of pure competition does not involve the assumption that at the time either tax is levied the specific tax is a percentage of market price which is equal to the rate of the *ad valorem* tax. See above, p. 80.

[19] It is clear that the tax would not alter the balance of economic attractiveness between markets I and II under any of the following assumptions: (1) that the tax were levied on the privilege of producing as distinct from the privilege of selling the product; (2) that the seller expected to have no further dealings in the product after he had disposed of his stock-on-hand; and (3) that the tax were levied only once in a fiscal period which was as long or longer than the relevant market and short-run periods combined.

[20] If the answer were Yes by all the sellers, market price would cease to exist.

2. *Monopolistic Competition*

Under conditions of monopolistic competition the seller must make his market and short-run decisions simultaneously, since any change in the volume of carry-over from market I to market II will effect a change in the price of his product in both markets. The pre-tax decision regarding the volume of sales in market I and the volume of production and sales in market II is the one under which the sum of the net returns in markets I and II is maximized. It follows, therefore, that the imposition and payment of a lump-sum tax of equal amount in both markets I and II will not cause the decision to be altered.[21] Since the tax is a lump-sum *sales* tax, it can be legally evaded by making no sales. For example, if no sales are made in market I no tax is paid in market I; and no *additional* taxes are paid in market II for the privilege of selling all or any portion of stock-on-hand in that market.

The seller will make no sales in market I if by so doing the reduction in the pre-tax sum of (1) gross receipts in market I and (2) quasi-rent in market II will be less than the amount of the lump-sum tax levied in market I.[22] The amount of the tax, the magnitude of the gross receipts in market I, the position and elasticity of the marginal revenue and marginal cost curves in market II are the factors concerning which the seller must have data before he can determine whether he would lose less by paying the tax in both markets and leaving his pre-tax allocations unchanged or by selling nothing in market I, paying no tax in market I, and altering volume of production and sales in market II. In the former case, market price would be unchanged; in the latter, it would cease to exist.

D. Net Returns Tax

1. *Pure Competition*

It is clear that the imposition of a proportional net returns tax will not alter the most profitable pre-tax distribution of stock-on-hand be-

[21] A seller who expected to sell only his stock-on-hand and then go out of business would sell none of his product if the lump-sum tax were greater than the largest possible gross receipts from his product. A seller who expected to remain in business over a period of time long enough to cover both the market and short-run period would close down if the amount of the lump-sum tax or taxes levied were greater than the sum of (1) gross receipts in the market period plus (2) quasi-rent in market II. Under such circumstances, he would, of course, dispose of his stock-on-hand if the lump sum tax levied in the market period were less than his largest possible gross receipts from the sale of his product. Under our assumption of identical demand and cost curves for all monopolistic competitors, any tax would affect all monopolistic competitors in the same manner.

[22] The seller will treat gross receipts in market I as net returns since the costs of producing such gross receipts are past costs.

tween markets I and II; and, therefore, will not affect either market or short-run price.[23]

The rate of progression of the tax on net returns might, however, be sufficiently steep to cause a change in the volume of sales and price in markets I and II. For example, let it be assumed that before the imposition of the tax the most profitable distribution of an individual seller's stock-on-hand was 50,000 units in market I and 5,000 units in market II. Let it also be assumed that sales in market I and market II would take place in two different fiscal periods. The sale of such a large percentage of the product in market I might yield net returns of a magnitude which would subject the seller to a tax rate so high in market I that his net returns, net of tax, would be less than if he were to sell less than 50,000 units in market I and more than 5,000 units in market II. If the tax affected in this manner a number of sellers sufficient to decrease appreciably the total volume of sales in market I, the negatively inclined market demand curve for the product of the industry would be cut at a point upward and to the left of the original point of market equilibrium; and market price would be increased.[24]

If the pre-tax distribution of the stock-on-hand of an appreciable number of sellers were such that they would sell a small percentage of their stock-on-hand in market I and a large percentage in market II, the imposition of a sufficiently progressive net returns tax would cause an appreciable reduction in the total volume of sales in market II, an appreciable increase in total sales in market I, and a *decrease* in market price.

2. *Monopolistic Competition*

If a seller has decided upon the most profitable pre-tax distribution of his stock-on-hand between markets I and II, the imposition of a proportional net returns tax would cause no change in volume of sales or price in either market. The pre-tax allocation of sales between the two markets would still yield the seller the greatest possible net returns, net of tax.

The imposition of a net returns tax with sufficiently progressive rates would, however, disturb the pre-tax allocation of product between and prices within the present and future markets. The reasons for this disturbance are the same as those which were given in the discussion of

[23] In this article, net returns means the excess of total monetary returns realized in any fiscal period from the sale of any quantity of product over the monetary rewards necessary to secure the services of the agents required for the production of that quantity of product. In what follows, it is assumed that the seller's total net income is from the sale of one commodity.

[24] It is conceivable that certain tax rate structures would result in a smaller total volume of sales in both markets than the seller's pre-tax allocations to these markets.

the effect on market price of a progressive net returns tax under conditions of pure competition. The fact that the reasons for the post-tax reallocation of stock-on-hand between markets I and II are the same under both pure and monopolistic competition does not mean, however, that the nature of the reallocation would necessarily be the same in the two cases. For example, under pure competition, the infinitely elastic demand for the product of the individual seller would make it impossible for him to decrease his realized net returns in either market I or II except by selling less in one market and more in the other. Therefore, the desire to decrease taxes paid in market II by an appreciable number of sellers will *always* be followed by an appreciable increase in total volume of sales in market I and a decrease in market price and conversely.

Under monopolistic competition, on the other hand, the degree of elasticity of the negatively inclined demand curves faced by the individual seller in markets I and II and the nature of the marginal cost curve in market II would determine whether a decrease or an increase in sales in either respective market would reduce realized taxable net returns and thereby increase net returns, net of tax.

USE OF FLEXIBLE TAXES TO COMBAT INFLATION[1]

By ALBERT GAILORD HART

Whether or not they are so intended, federal tax collections and expenditures unavoidably have profound monetary effects. Taxes may be regarded as analogous to Federal Reserve open-market sales, expenditures as analogous to open-market purchases. But besides being on a much larger scale than Federal Reserve operations, Treasury operations are more powerful, dollar for dollar. Federal Reserve operations are purchases and sales of securities which are almost perfect money substitutes. But the objects of Treasury operations are very unlike money. What the Treasury "sells" when it collects revenue is tax receipts; its purchases range from planes and typewriters to cancelled checks for old-age assistance. While Reserve operations affect only the composition of the public's capital assets, Treasury operations impinge, furthermore, on income accounts. Both these differences give Treasury operations powerful leverage.

It is no novelty to suggest that since federal budgeting has monetary repercussions it should be guided partly by monetary objectives. Manipulation of federal expenditures to stimulate employment has been practical politics ever since 1933; and manipulation of taxes is a familiar idea at least to academicians. But the war emergency calls for a shift in emphasis. Since the middle of 1940, defense has gripped the expenditure side of the budget, and monetary considerations can no longer affect the bulk of federal spending. If the budget is to be used consciously for monetary control—which at present means to check inflation—flexibility must be on the revenue side.[2]

The Treasury, the Congress and the general public are of course familiar with the idea that taxes are anti-inflation weapons—an obvious lesson of the world's long list of experiences with inflationary war finance. But the application of this idea in American public policy has taken the form merely of a rule of thumb—Secretary Morgenthau's

[1] The writer is indebted to his colleague E. D. Allen for criticism and suggestions.

[2] The writer does not mean, of course, that federal powers over the monetary situation are confined to taxation. Not to mention credit controls, a government borrowing program which stimulates saving can do a good deal to check inflation. But effects upon saving are likely to be second-magnitude unless loans are made compulsory; and compulsory loans may be regarded as sweetened taxes. (*Cf.* the writer's paper on forced loans at the Philadelphia meeting of the Tax Institute, Dec. 1, 1941, appearing in the forthcoming volume on *National Defense and Taxation.*)

rule of covering two-thirds of expenditures by taxation—and even this rule has not so far been made effective. Viewed as a standard for monetary policy, this is plainly inadequate. Economists should consider carefully whether it is not possible to recognize monetary needs explicitly as a guide to tax policy, and to reshape the federal tax system to permit following that guide.

I. Tax Mechanism for Monetary Control

In present circumstances, the monetary use of taxation means draining off spending power until the remainder is brought into line with consumer goods output. As we shall see presently, the scale of this drain must be enormous. Consequently its fair apportionment among the population is very important.

In view of the prospect that total consumption, in physical goods terms, must fall rather than rise during 1942, "fair apportionment" implies that nobody can expect to be left in a position to increase his consumption unless he is increasing his output, and that even people who increase their output cannot expect to increase consumption unless either their present consumption standard is very low or their contribution to added output very great. The only way to apply this rule is through income taxes.

The Timing Difficulty

Since the Treasury announced late in November that no further increase would be made in taxes on 1941 incomes, the regular income tax revenue of 1942 has been a settled thing; for taxes on 1942 incomes will not begin to come in, in the regular course, before March of 1943. While taxes collectible in 1943 will not be completely ineffective in 1942, their influence is somewhat unreliable,[3] and may even work in the wrong direction if they encourage individual households to stock up before their surplus over current needs is cut into by taxation.

One possible way to avoid this time-lag, of course, is to turn away from income taxes to sales or wage taxes, both of which are prompt in collection. But aside from the powerful arguments in equity against these taxes as major sources of war revenue,[4] it must be remembered

[3] *Cf.* U. K. Hicks, "Lags in Tax Collection," *Rev. of Econ. Studies*, vol. viii, no. 2 (Feb., 1941). Increasing 1942 corporation taxes will of course influence dividends during 1942; but unless earmarked cash is held against these taxes spending power may be increased through business investment. Individuals apparently react to taxes as they become payable, not as they accrue.

[4] The heavy burdens imposed by existing taxes of these and other regressive types upon low-income taxpayers are shown in Twentieth Century Fund, *Facing the Tax Problem* (New York, 1937); G. Colm and H. Tarasov, *Who Pays the Taxes?* (T.N.E.C. monograph no. 3, Washington, Supt. Docs. 1940); and A. G. Hart, E. D. Allen, *et. al.*, *Paying for Defense* (Philadelphia, Blakiston, 1941). A fresh analysis of the problem of estimating tax

that both create powerful stimuli to demands for wage increases; while sales taxes, under present conditions, constitute price increases in themselves.

A Currently Collected Defense Tax on Individual Incomes

To combine the virtues of promptness and fairness calls for a currently collected tax on individual incomes—taxing 1942 incomes in 1942—along the lines proposed by the Treasury late last year. Following Canadian precedent, it would be most appropriate to label such a tax a "National Defense Tax." While such an innovation involves serious administrative difficulties,[5] they are no worse than those involved in alternative procedures; and since a tax of this character has permanent value, the work of solving these difficulties will not be wasted in the long run.

The basic technique of prompt collection is to withhold tax at the source of income wherever feasible—*i.e.*, for corporate dividends, for corporate and government interest payments, for other forms of property income wherever handled by fiduciaries or agents, and for the excess of salaries and wages over exemptions. For taxpayers whose income cannot be reached at the source—*i.e.*, for self-employed business and professional men, farmers, owners of rental housing, etc., possibly for employees of very small firms—a workable substitute can be found by requiring quarterly payments based on the annual income tax return for the previous year. Exemptions under Defense Tax should be fixed, as they are in Canada, below the regular income tax level—perhaps at or below $1,000 for a head of family.[6]

Equalization

Under a promptly collected tax, the final tax liability of each taxpayer cannot be computed precisely at the time of collection, but only approximated. Inequities among taxpayers of like income and family status can be cleared up, however, by an annual equalization at the time regular income tax returns for the year are filed in the following March. This equalization will involve extra assessments for some taxpayers, tax credits or small cash refunds (presumably through redemption of stamps) for others.

burdens is being prepared by C. Hildreth and the present writer for a projected statistical bulletin.

[5] For the nature of the difficulties and a demonstration that they are soluble, see Dr. Walter Heller's paper for the Tax Institute meeting of Dec. 2, 1941, Dr. Heller's memorandum filed in the Senate Finance Committee's *Hearings . . . on Revenue Revision of 1941* under date of August 13, 1941, the present writer's memorandum in the same place, and *Paying for Defense*, chap. XVI.

[6] On the need of lower exemptions, see *Paying for Defense*, chap. XV, and the forthcoming statistical bulletin referred to above.

The chief question of principle in planning an equalization procedure is whether to base both Defense Tax and regular income taxes on the same definition of "net income," or to permit deduction of one tax in computing net income taxable under the other. On the former system, which would be the present writer's first choice, the sum of Defense Tax and "normal tax" rates, plus the highest applicable surtax rate, would give marginal rates exceeding 100 per cent for some taxpayers as soon as Defense Tax exceeded 21 per cent. If all such combined rates exceeding 100 per cent were treated as *equalling* 100 per cent, the effect would be to impose a ceiling on the income left after tax. This ceiling would fall automatically as Defense Tax rose.[7]

Given a powerful tax of this type, the government would be armed with an effective weapon against inflation. A prompt and substantial revenue response would flow from any change in the level of tax rates or exemptions. Even with unchanging rates and exemptions, such a tax offers a limited automatic adjustment against inflation; for, with rising nominal income levels, not only a larger amount of income but also a larger proportion of the total would become taxable.

II. Criteria of Policy

Supposing a tax mechanism of this sort to be in working order, how should it be used? Since we are starting from a tax level below that necessary to check inflation, and since rising arms production implies an increasing inflationary pressure, we may safely answer, "More and more!" But to make this answer more precise calls for examining the objectives of policy.

Three Objectives

Monetary and fiscal policy should evidently aim toward:

1. A large volume of war production.

[7] Here are a few sample results:

Combined Defense Tax and Normal Tax Rate	30%	40%	50%
Level of "surtax net income" above which marginal rate is 100%	$300,000	$70,000	$32,000
Surtax at that level, 1941 rates	183,280	30,980	9,900
Normal tax, allowing maximum earned income	11,944	2,744	1,224
Defense Tax, assuming regular income tax exemptions	78,000	25,200	14,720
Residue of surtax net income	$ 26,776	$11,076	$ 6,156
Total net income, after taxes, adding in typical exemption (for head of family plus two dependents)	$ 29,076	$13,376	$ 8,456

These results somewhat understate the maximum amount left after taxation, since part of income-tax "deductions" are actually expenditures of which the taxpayer gets the benefit. This applies particularly to mortgage interest and property taxes of home-owners.

2. Within the limits of resources not needed for the war, a large volume of civilian production.
3. Avoidance of inflationary price increases.

As among these objectives, the first has a clear priority. As between the second and third, the second is presumably more important; but most economists would probably recommend sacrificing it to some extent to the third, if conflict arises.

Both production objectives, for reasons well known to economists, are likely to be favored by rising prices. Hence they may call for mild inflation, conflicting with the price objective. Since the impact of government spending is directly upon war production, however, even a very drastic tax program aimed to block inflation will not take hold very strongly in this field. The fiscal policy issue is principally between the price objective and civilian production.[8]

Price Dispersion and the Level of Civilian Prices

The degree to which price and production objectives conflict turns largely on the dispersion of prices. The presumption that a rising price level favors employment rests on the observations that prices do not all move parallel and that *absolute* price decreases are hard to achieve in many fields without unemployment. In short, to keep employment at a high level it is desirable that few absolute reductions of prices be called for. But since *relative* price adjustments must take place, it is a matter of arithmetic that, if there are fewer absolute decreases, there must be more absolute increases. Stabilizing the relatively falling prices implies raising the general index. How much the general index must rise depends partly on the dispersion of relative price movements, partly on how tenderly we wish to treat the relatively falling prices.

In the actual situation, it is plain that there is an upward drift in the prices of metal products, rubber products, silk stockings, woolen clothing, foods suitable for Lease-Lend shipments, and housing in defense areas, relative to more bulky and perishable foods, amusements, cotton clothing, and rents outside defense areas. This relative price shift has some value in drawing resources into the critical branches of production and diverting purchases to things which are relatively easy to

[8] Deflation in the sphere of civilian production can make indirect contributions to war production by creating unemployment and thus increasing incentives to find uses for men and equipment in war production. American history provides a shining example of the military value of unemployment in the naval efforts of the Revolution and War of 1812, when unemployment among sailors and fishermen created a formidable fleet of privateers, besides helping naval recruiting. But deflation is not properly selective in its pressure upon civilian industry, taking no account of the extent to which resources can actually be shifted to defense. The use of priorities and direct output restrictions (like that upon automobiles) in lines where resources are highly transferable has all the military advantages of deflation, without all its disadvantages for consumption.

produce, and still more as the only available procedure for deciding who is to get scarce goods, in the absence of consumer rationing.[9] Unless a widespread rationing system is to be adopted, these relative changes cannot and should not be resisted. If their income-effects on the sellers of the goods in question are unwelcome, the appropriate remedy is a system of excises-à-la-Henderson (in effect, special excess-profits taxes), applying to goods made scarce by war.

Suppose that the general rule is to try to prevent a downward drift of absolute prices from becoming so widespread as to affect more than 10 per cent of the weights of the B.L.S. cost-of-living index. If the average rate of downward drift for these falling prices is not to exceed, say, 2 per cent per month, the average monthly rate of increase for the other nine-tenths of the index cannot much exceed 0.2 per cent per month without raising the total index. This is a rather modest allowance, so far as the writer can judge. To give room for appropriate relative adjustments, without a serious proportion of absolute declines, is likely to call for an average monthly increase of 0.2 per cent to 0.5 per cent in the cost-of-living index.[10] If the price dispersion proves greater than this estimate implies, the rate of rise in the index required to keep down the weight of absolute decreases may pass the critical level (probably between 0.5 per cent and 1.0 per cent monthly[11]) at which price increases generate a "spiral." In this event, a clash between price and production goals cannot be avoided.

Administered Prices

The likelihood of such a clash is enhanced by the large element of "administration" in the determination of many of the wage rates and

[9] Until the last few weeks, journalistic advocates of "price control" as the remedy for inflation have shown no signs of realizing that we cannot simultaneously (1) have a national shortage of a commodity, (2) prevent its price from rising, and (3) let every buyer purchase all he chooses—*i.e.*, reduce the total of consumption without reducing any of its parts. This curious arithmetical error made price control appear as the last stronghold of "business as usual."

With the actual beginning of consumer rationing, price control begins to be seen more in perspective. But there still seems to be little realization that rationing must cover the bulk of consumer spending to be an effective barrier against inflation, and that tires, automobiles, and sugar cover only a very small sector. British experience indicates that the mere organizational difficulties of rationing will keep it from being very effective against inflation during 1942.

[10] This is frankly a guess. Studies of price dispersion in the period since February 1941 might improve it; but it is hard to evaluate the effect of our actual involvement in the war. We are operating so far outside the range of recent experience that the writer is very skeptical about the possibility of an accurate forecast of the necessary price dispersion.

[11] Increases more rapid than 0.5 per cent monthly in the B.L.S. cost-of-living index never continued long enough to show up in the recorded figures between 1920 and 1939; but through most of World War I the rate of increase exceeded 1.0 per cent monthly. See *Paying for Defense*, p. 182.

farm prices which constitute costs of production for producers of civilian goods. Even though more man-hours of coal-mining labor, or more wheat, could readily be found for sale at existing prices, the United Mine Workers in the one case and the federal government in the other are quite capable of raising miners' hourly rates and the price of wheat. In so far as the costs "administered" to higher levels are those of the civilian goods labeled above as relatively falling, maintaining the output of those goods comes to depend on an absolute increase in their prices. To prevent a decline in employment then calls for a corresponding acceleration in the rise of the general index, and the danger of a spiral is accentuated.

Since the people who "administer" prices keep one eye on the market, taxation can do something to block increases of this sort. General taxation of personal incomes, draining off spending power, will hold down profits; and excess profits taxes will catch the more conspicuous profits as earned. Still further, success of income taxation in checking the rise of living costs will reduce the demand for countervailing rises in money incomes. Thus tax policy can create a setting for a "reasonable" settlement of demands for higher wages and raw materials prices. But the primary responsibility in this field is not upon the monetary authorities but upon the government agencies and economic interest groups directly involved. To get the maximum benefit from monetary and fiscal measures against inflation, wage-rate increases should be discouraged unless the union demanding them can show (1) that a shortage exists and more man-hours of qualified labor cannot be had at existing rates; (2) that the union itself is not creating the shortage by its own exclusive policy or restrictive working rules. On the side of farm prices, where "administration" is actually done by the government, the rule should also be to avoid increases except where a shortage exists and where the shortage is not itself created to boost prices. In both fields, of course, many specific increases are urgently needed to increase supplies; prominent examples are cheese prices and seamen's wages.

Giving Ground before Administered Prices

If the groups responsible for holding down the administered prices do not keep them in check, most students of monetary problems would probably agree that monetary and fiscal policy should give ground and permit a corresponding upward drift of prices. Taxation should not be relied upon to stop price increases based on trade-union or farm-group action.[12]

If we constructed an index number of cost-prices underlying the pro-

[12] In the terminology of J. M. Keynes's *Treatise on Money,* monetary and fiscal measures are effective against "profit-inflation" but not against a spontaneous "income-inflation."

duction of civilian goods, under such conditions, it would have an upward drift for two reasons: (1) as with finished-goods prices, there is a natural dispersion of changes in cost-prices, and the relatively-falling group cannot be pushed wholesale into absolute decreases without adverse effects on employment; (2) as we have just seen, "administered" cost-prices in the relatively-falling group are likely in fact to be pushed upward from the supply side.

To a first approximation, the task of fiscal policy may be defined as the stabilization of the cost-of-living index—not absolutely, but relative to an index of cost-prices so composed and so weighted as to represent cost-prices affecting different consumption goods in the same proportion that the prices of the latter enter the cost-of-living index.[13]

This first approximation rule, however, may lead policy astray for two chief reasons: (1) the sheer technical defects of the index numbers used might be serious enough to give their ratio a misleading drift; (2) the relation of prices of materials and labor services to per-unit costs may be considerably altered by wartime changes in industrial patterns. Any policy based on the ratio of the two index numbers should therefore be at least slightly modified in the light of employment figures. If there came to be noticeable unemployment of types which defense could not absorb but freer consumer spending could, it would be desirable to set taxes lower than the formula would indicate. On the other hand, if employment were satisfactory while cost-prices and selling-prices were rising in line with each other, it would be worth imposing heavier taxes in hope of checking the cost-price advance.[14]

Relative Drift of Costs and Selling-Prices

The argument above limits the rôle of fiscal policy to keeping prices of civilian goods in line with their cost-prices. But this limited objective is very important in itself. For 1942, we must expect a substantial rise in national income relative to our supposed cost-price index, resulting from increased employment, longer hours, "upgrading" of laborers and similar shifts which contribute to the physical volume of total output. But while a corresponding rise in total output is scheduled, the war effort will not only absorb the increase but bite deeply into present

[13] This redefined price objective has a strong formal parallelism to agricultural "parity." But its implications for income distribution are very different, since it is thought of as enforced by manipulating an income tax rather than by manipulating the flow of goods to consumption.

[14] This presumption for a downward drift of selling-prices *relative to cost-prices* does not contradict our original argument for permitting a rise of selling-prices on account of price dispersion. Implicit in the original argument was an assumption that dispersion among cost-prices implied an upward drift in their average; and the allowance for an upward drift of cost-prices made in this section of the text thus takes care of the dispersion of selling-prices.

civilian supplies. Even if wage rates and so on did not increase, we should have increased spending power confronting reduced civilian supplies. This would certainly raise living costs.

The danger of spiral inflation lies in the fact that as living costs rise *relatively* to wages, wages tend to rise *absolutely* in a vain attempt to compensate. We have seen enough in 1941 to be clear that the danger of a spiral "income inflation" is no mere bugbear, even though full employment is not yet reached; and rising employment will further increase the danger. Choking off the relative rise of living costs is an essential part of the remedy.[15]

III. Necessary Revenues and Tax Rates

To hold inflation in check, we shall need more taxes to drain off spending power. But how much more? So far, the only answer offered by this paper is qualitative: enough to restrict the price rise as narrowly as possible, in view of price dispersion and the behavior of administered prices, without excessive unemployment.

Our monetary situation is packed with uncertain factors. We cannot accurately forecast, for example, the course of bank credit or the future of saving and of private investment.[16] Accordingly, no clear-cut answer can be found in advance of experience; and in the end the solution must be found by cut-and-try methods. But it is both possible and urgent to estimate the general order of magnitude of the requirements.

War and Consumption

To begin with figures of relative certitude, we spent rather over 12 billion dollars in defense in calendar 1941. In view both of the rapid acceleration during 1941 and of our actual involvement in the war, it is conservative to estimate that our war effort will absorb 20 billion dollars worth more in 1942 than in 1941, at 1941 prices. Our economy will also produce more—presumably by 10 to 15 billion dollars. Making optimistic allowances for the effect of increased total output and of drafts on private investment, it is hard to believe less than 5 billion dollars worth of the added war effort must be at the expense of consumption goods.[17]

[15] This assumes, as does most of the argument of this article, that we are not going to set up a full-blown rationing system at once.

[16] For an inventory of sources of uncertainty, see the writer's paper on "Safeguards against Inflation," *Rev. of Econ. Statistics*, May, 1941, pp. 85-86.

[17] Needless to say, the cut in physical consumption is not logically a mere residual. Large masses of resources used in 1941 for consumption (conspicuously for metal products) are both adaptable to defense and nonessential for civilian use. These must be transferred. On the other hand, we have some resources (chiefly in farming) which are specialized for consumer goods uses and will be more fully used in 1942. Increased flows of food, amusements, etc., will presumably go part way to offset transfers of metals, chemicals and textiles to defense. But 5 billion dollars is a conservative estimate of the net loss to consumption.

While the war will reduce physical output of consumption goods, it will increase money incomes. The increase in total production assumed above implies a rise of 10 billion dollars or more in money incomes, at 1941 wage rates, etc. Of this increase, 6 or 7 billion dollars would normally be added to spending. With 1941 tax revenues, 1942 spending would thus be 11 billion dollars or more too high relative to 1942 consumption goods output. If a price rise relative to wage rates of, say, 5 per cent is to be tolerated, there will yet remain some 7 or 8 billion dollars of excess spending to be disposed of.

In addition, if income taxes are to be the means of adjustment, we must allow for inter-group shifts of consumption. Assuming a 100 billion dollar national income and a $1,000 head-of-family exemption, at least 2 or 3 billion dollars of the income increase will accrue to people who remain below the taxable family income level.[18] The principle of ability-to-pay taxation implies letting families below exemption limits keep and enjoy any income increase they can capture. The income-tax-paying groups, therefore, must absorb not merely the whole cut of total spending but also a further cut to permit an expansion of at least 2 billion dollars in lower-income-bracket consumption. The total cut in spending required of income-tax payers is thus at least 9 billion dollars relative to what they would normally spend with their 1942 incomes, or perhaps 5 billion dollars relative to their spending in 1941.

Revenue Requirements

When a family's income is reduced, the effect is divided between a reduction in spending and a reduction in saving. For families in the income-tax brackets, much of the effect is bound to be upon saving. While no definite forecast can be entirely safe, it is very unlikely that the curtailment of savings will be less than a third of the taxes levied.[19] To reduce spending by 9 billion dollars thus calls for at least 14 billion dollars of additional revenue in 1942, compared with 1941.

Of the 14 billion dollars, about 7 billion dollars can be expected from revenue measures in force at the end of 1941—divided about equally between effects of 1941 enactments and effects of rising income levels.

[18] It must be borne in mind that a $1,000 head-of-family exemption gives a normal family with two children $1,800 of tax-exempt net income; and with allowance for "deductions" of normal proportions this means that such families will rarely be taxable unless total cash income exceeds $2,000. On a comparable exemption basis for a 90 billion dollar income, *Paying for Defense* (p. 148) finds 56.3 billion dollars (62 per cent) accruing to persons taxable. The effects of a higher general level of incomes in carrying more people above exemption limits are roughly balanced by the assumption in *Paying for Defense* of a $200 credit per dependent, instead of $400.

[19] In *Paying for Defense* (pp. 128-29) the effect of a similar type of tax is estimated to be half upon spending and half upon saving. The sharper effect on saving assumed here reflects partly the larger scale of the tax in question and partly the intentional bias of the calculation here in progress toward understating tax requirements.

Another 1 billion dollars or so may be looked for from special excises of the type proposed by Leon Henderson, upon goods made scarce by defense. This leaves 6 billion dollars to be found by the proposed Defense Tax, at a minimum figure. In view of the prognosis for a continued rise of production and incomes well through 1942, it is probable that requirements will be heavier in the second half-year than the first.

Tax Rate Requirements

Since the proposed exemption level is well below the range of income tax experience of the federal government, the amount of income which would be taxable under Defense Tax is hard to estimate. If taxpayers enjoy two-thirds of the national income, about 33 billion dollars is likely to be taxable.[20] The 6 billion dollars of Defense Tax revenue mentioned above would thus imply an 18 per cent rate of tax. For every additional billion by which spending had to be curtailed, an additional 5 per cent or more of Defense Tax would be needed, unless exemptions were further lowered.

Probable Errors of Estimation

The estimates presented above have intentionally been given a bias toward understatement of tax requirements. Comparatively modest changes in the figures would make the tax rates called for look much more formidable.

To begin with, it would not be unreasonable to put the decrease in consumer goods output compared with 1941 at 6 instead of 5 billion dollars, the increase in money incomes (at 1941 wage-rates, etc.) at 11 instead of 10 billion dollars, the increase in spending at 8 instead of 6 billion dollars. This would raise the excess of spending to 14 instead of 11 billion dollars. After allowing a modest price increase, there would still be a net excess of 11 billion dollars or so. The additional consumption of the low-income groups not reached by tax could easily be put at 3 instead of 2 billion dollars, so that taxpayers must be called upon to cut spending 14 billion, instead of 9 billion dollars. If we put the effect of taxes on saving at 40 per cent instead of 33⅓ per cent, the additional taxes called for would be 35 billion dollars, or 28 billion more than existing measures will yield.

On this revised set of hypotheses, which is no more extreme in an upward direction than the previous set in a downward direction, the Defense Tax could not block inflation at any tax rate whatsoever,

[20] Of the 56.3 billion dollars shown as accruing to taxpayers under the roughly comparable situation sketched in *Paying for Defense*, p. 148, 30.3 billion dollars is absorbed by understatement, non-cash income exempt from tax, deductions, and exemptions, leaving rather less than half taxable. This proportion taxable should rise somewhat with national income at a higher level.

without a further reduction of exemptions. Even cutting exemptions to half the level suggested would probably not increase the tax base to much over half the national income, so that more than half of all taxables might have to be taken.[21]

Effects on Business Savings

In the argument above there is an implicit assumption that changing taxes upon individual incomes will not deter corporations from paying out a normal proportion of their profits. There are considerable indications, however, that even 1941 rates had such an effect; and the rates of Defense Tax mentioned above would doubtless intensify it. Whether dividends fail to reach the stockholder because they are not paid out or because they are taxed away, his spending will be reduced. But corporate savings, since they build up assets for the stockholder, will displace his individual savings more than would taxes of equal amount, while affecting spending less.[22]

Per billion of revenue actually raised by a Defense Tax, the effect upon spending would be greater than the estimates above would suggest. But per point of tax the effect might or might not be greater. If, say, a $1,000 dividend payment was withheld to avoid $250 of Defense Tax, the effect on a middle-income stockholder would probably be to reduce his personal savings by, say, $500 to $950, and his spending by $50 to $500, according to his situation. The effect on spending might or might not be greater than if the dividend and the $250 tax were both paid.

To avoid inequities between stockholders who were and were not able to avoid taxes by letting corporate incomes be plowed back, some device for taxing undistributed profits to the stockholders would be needed. Such taxation is thus a corollary of a Defense Tax upon incomes, if Defense Tax rates are to be substantial.

IV. Fiscal Management under Mandatory Rules

The criteria of policy discussed above would be suitable for a discretionary authority backed by the full confidence of the Congress and the public. They might conceivably serve Congress if it were decided to make frequent adjustments in Defense Tax by special enactment. But they call for so much exercise of judgment in application that they could not well be used directly as a basis for mandatory instructions to the Treasury.

[21] At this very low exemption level, the great bulk of the population would be taxable. But exempting $250 per adult plus $400 per child would still remove a large fraction of the national income from taxation, not to mention the huge losses of tax base through understatement, failure to tax non-cash income, and deductions.

[22] The effect of corporate savings is analogous to that of forced loans.

The question now arises whether a working substitute can be devised which will lend itself to mandatory arrangements. In short, we must look for a formula which is at once:

1. Definite enough to limit Treasury discretion and if possible to forestall litigation;
2. Simple enough to be explained to the general public;
3. A good approximation in its effects to operation under the criteria described above.

Pre-Determined Rates

The established system of revenue-raising is of course to pass a tax with definite pre-determined rates. These rates may be set until further notice, or they may be enacted on a step-wise system, with an increase to be effective at some stated future date.

As we have noted, even a flat-rate tax to apply through the war period would mitigate inflationary pressures. At a 100 billion dollar level of income, 1 per cent of tax represents an annual revenue between 300 and 350 billion dollars. As nominal income rose through inflation, not only the absolute revenue but also percentage of national income drawn in would rise somewhat. But if the initial rate were far short of what was required to stop inflation, this automatic braking effect would be far too small to bring the price level to rest within any measurable period.

In view of the prospect of increasing expenditures and of the political tendency to take off the little dog's tail in two bites rather than one, provision for a rate increase at some pre-determined future date is a relatively likely arrangement. So long as this prospect is not made an excuse for inadequate initial rates,[23] such a system will improve the time-shape of the tax revenue. With perfect foresight, it might even be made to serve all the purposes of fiscal policy. But in view of the gigantic uncertainties already noted, there is no use expecting to lay out an optimum timetable of taxation in advance. Pre-determined rates cannot do the job adequately, for lack of flexibility.

Price-Index Formulas

If a discretionary authority is ruled out, the economist's natural first thought for a flexible arrangement is a price-index formula. The present writer has made suggestions along this line on several occasions.[24]

[23] As Homer Jones points out in his paper for the Tax Institute meeting of Dec. 1, 1941, there is not much sense in the idea of introducing heavy taxes gradually "because they are so painful," in view of the painfulness of the alternatives.

[24] *Economic Policy for Rearmament* (Chicago, 1940, pp. 26, 33); House Ways and Means Committee, *Hearings . . . on Revenue Revision of 1941*, pp. 335-36; *Paying for Defense*, chap. XVII.

If we could assume that wages and farm prices were stable, except as relative increases helpful to defense took the form of absolute increases, such a price-index formula ought to turn out reasonably well. But as the argument above has indicated, a tendency toward "income inflation" through organized pressure on cost-prices would require complicating the formula and basing it on the relation of two index numbers rather than on one alone. This procedure is both unduly hard to interpret to Congress and the public and also liable to give undue weight to idiosyncrasies of the index numbers selected. In addition to this defect, there is a serious political defect—the danger that the mere presence of a tax formula geared to living costs would accentuate wage and farm-price pressures.[25]

Government-Expenditure Formulas

Less congenial at first thought to an economist, but still very promising economically, are proposals in political quarters for formulas hitching tax rates to government expenditures. These have been framed in terms of annual adjustments to secure an "automatically balanced budget."[26] But there is no reason why this type of formula should not be applied both to standards of coverage below 100 per cent (for instance to the Treasury's two-thirds rule) and to quarterly or even monthly adjustments. The Treasury could be required to set a Defense Tax Rate for the oncoming three-month period which would bring total receipts up to any specified percentage of total outlays for the period. It would be possible also to provide for automatic lowering of exemptions to widen the tax base if necessary. Exemptions could be lowered either step by step as rates rose, or only after rates had reached a certain ceiling, say 40 or 50 per cent, without satisfying revenue requirements.[27]

[25] This point was emphasized by Carl Shoup in his "Choice of Tax Measures to Avert Inflation," *Rev. of Econ. Statistics,* May, 1941, p. 89. If anything, it is more serious if wage rates and farm prices as well as living costs enter into the formula.

[26] One such proposal, apparently not much noticed by economists, already has a legislative history. A resolution (S. R. 22) was agreed to by the United States Senate on Feb. 13, 1941, creating a committee of three "to find ways and means for an automatically balanced budget." This committee (consisting of Senators Tydings, Thomas and Holman) reported two months later, submitting two draft bills and a draft constitutional amendment as a basis for discussion. One of these bills (in a Committee Print of April 29, 1941, numbered J.313715-A) proposes enacting fifteen alternative schedules of taxes, each framed to raise 5 per cent more revenue than that preceding it on the list, and giving the Treasury mandatory instructions to put into force at the beginning of each year that schedule which will raise "the required amount of revenue" according to a standard set up in the bill.

[27] While Senator Tydings' tentative scheme does not confine itself to income taxes, the illustration of a difference between successive tax schedules which is presented in the committee report runs in terms of lowering income-tax exemptions.

The Danger of Taxing Too Much

The economist's natural hesitation to endorse such a government-expenditure formula or "automatically balanced budget" springs from his knowledge that it is possible to tax too much. Under unfavorable conditions, attempts to balance the budget may increase unemployment (and incidentally may defeat their budgetary object by doing so).

But taxing too much is not the number one danger of the year 1942. Taxes on the books in December 1941 are expected to bring in about 14.5 billion dollars (cash basis) for the fiscal year 1941-42 or about 18 billion dollars for calendar 1942. At the lowest defensible estimate of outlays, this means covering out of taxes 45 per cent of outlays for the fiscal year, or 37 per cent for the calendar year. The 6 billion dollars of Defense Tax mentioned above as minimum requirement would bring tax coverage for calendar 1942 to about 49 per cent; to bring it to 90 per cent would take a Defense Tax of over 25 billion dollars. Even at a 90 per cent coverage, moreover, the cash deficit would be about as great as it was in the late winter of 1941, when inflation began to take hold.

A Safeguard against Over-Taxing

In any event, a simple safeguard against taxing too much can be set up by introducing a single discretionary element into the system.[28] The Treasury should be authorized to fix a lower rate than that called for by the formula, on the basis of a double finding of fact:

1. During the latest three months the B.L.S. living-costs index averaged not more than 1 per cent above its level in the last preceding three-month period; *and also*
2. During the latest three months, nonagricultural employment averaged either:
   a. Less than at the end of 1941 or
   b. As much as 1 per cent below the last preceding three-month period.

In such a situation, this limited exercise of discretion could scarcely be objectionable.

Needless to say, such an escape clause could come into play only if the proportion of outlays covered by taxes was very large. But the existence of such a clause would make it safe to aim high—even at 100 or 90 per cent of expenditure. There would be no advantage at all in fixing the proportion to be covered below 80 per cent. Thus such a policy

[28] This ingenious device for combining the simplicity of an expenditure formula with the substantive advantages of a rather complex price-index-employment formula was suggested by the writer's colleague Walter W. Wilcox.

would permit holding the growth of public debt to the minimum compatible with high levels of production.

Flexibility under Rules

This system of mandatory rules promises the advantages of a discretionary system on the lines outlined earlier in this paper, with a minimum of confusion in administration and public relations. It is calculated to provide the maximum anti-inflationary effect which taxes can yield without damaging production. If the "administered" prices are properly handled, it is capable of keeping the pace of price rise close to the rate below which the safeguard comes into play—presumably below the critical rate of 0.5 per cent monthly, once collection mechanism and rates are in force.

The two basic ideas involved are simple and close to the views of the general public:

1. It is desirable to "pay as we go" and limit the growth of public debt;
2. It is desirable to keep the weight of taxation from creating avoidable unemployment.

Either of these ideas alone is somewhat dangerous (the second, at present, more than the first). But a compromise along these lines should be workable both politically and economically.

FISCAL POLICY AND THE NATIONAL INCOME: A REVIEW

By CHARLES O. HARDY

Professor Hansen and Professor Villard have written books[1] which deal with the same theme—the use of national fiscal policy to control the levels of money income and of employment and productive activity. They are based in general on the same fundamental assumptions, such as the causal relation running from money income to real income; the tendency of an increase of saving to pull down money income and an increase of investment to increase money income; the extreme importance of stabilizing employment at a high level, and of reducing present inequalities of economic power; the probability that income taxes will tend to be paid out of savings and consumption taxes out of income that would otherwise be consumed; and a strong propensity for total income to decline from year to year in the absence of a public policy to stimulate expansion.

The two volumes bring home to us forcibly the instability of political-economic relations. Both are penetrating analyses, written for scholarly audiences, and combine a broad scope with careful attention to detail, and both were published in 1941. Yet neither author thought it worth while to give more than passing notice to the phase of his subject which by the end of 1941 was the principal topic of discussion; namely, the prevention of an unduly rapid rise of money income. For both authors, the fiscal and monetary problem was the prevention of deflation.

Obviously, if public expenditures are to be effective as an income stimulant they must be so financed as not to decrease other expenditures accordingly. Hence the choice for both authors is between deficit expenditures financed by borrowing from banks with excess reserves or from holders of capital balances (or conceivably by the issuance of paper money), and taxes that do not decrease either private consumption or private investment. Villard's emphasis is on deficit financing, the estate tax being the only important tax which he finds free from a suspicion of having "income-decreasing" effects. Hansen, however, is more concerned about the possible future disadvantages of the accumulation of government debt, the piling up of idle money in private

[1] *Fiscal Policy and Business Cycles.* By Alvin H. Hansen. (New York: Norton. 1941. Pp. ix, 462. $3.75.)

Deficit Spending and the National Income. By Henry Hilgard Villard. (New York: Farrar and Rinehart. 1941. Pp. ix, 429. $3.50.)

hands, and the indefinite lowering of interest rates; hence he pays more attention than does Villard to the possibility of financing income-creating expenditures through taxes that do not decrease private expenditures.

Both books contain good sketches of the history of post-war monetary policy, and both reach the conclusion that monetary policy alone is insufficient to bring about recovery from a deep depression, whereas fiscal policy is an adequate instrument. I am not prepared to dispute either conclusion, but both books leave me with the impression that monetary policy has lost the vogue which it had in the twenties, and fiscal policy has gained popularity, largely because monetary policy has been appraised by what was not accomplished, and fiscal policy by what was accomplished, during a period when both were being used together. If the slowness of recovery in 1933-39 discredits monetary policy as an instrument of control, the rapidity of recovery in the same years can hardly validate fiscal policy for the same purpose.

Both authors include state and local finance in the scope of "fiscal policy." Villard presents as an appendix an able original study of state and local deficit financing for recent years. Valuable as this material is for the use of students of public finance, I believe it has little bearing on the main theme, the relation of fiscal policy to the formation of income. State and local finance cannot properly be used as an instrument for controlling the level of income, for the simple reason that the costs of such a policy are localized and the benefits are diffused. In this respect, local finance is like individual and corporation finance. Expenditures by the national government may be justified by their effect on the national income, but an individual corporation, or a municipality, or a state, acting independently of others, cannot make expenditures and expect that it will be compensated by an increase of its income resulting from the stimulated increase of general income. The difference between national and local finance parallels the difference between central banking and private banking. Deficit spending for the sake of income-stimulation is practicable only for a national government, and probably only for that of a large country.

Multipliers.—Both Hansen and Villard devote much space, naturally, to the nature of the multiplier, and both make valuable contributions to the understanding of this knotty problem. Hansen presents an illuminating series of hypothetical model sequences, combining the effects of the multiplier and the acceleration principle. Villard criticizes half a dozen other writers' work, and contributes an excellent discussion of the character of "leakages."

With respect to statistical *ex post* calculations of the actual multiplier, Villard's treatment is less satisfactory. On page 232 he comes

very near to saying that such calculations are worthless, a conclusion with which I am inclined to agree. Any such investigation involves comparing an unknown product (the difference between actual income and what income would have been in the absence of the deficit), with a partly known multiplicand (the part of government expenditure which is financed by non-income-decreasing borrowings or taxes), on the basis of the general income velocity of money, which may or may not be the same as the marginal income period of new money.[2]

But Villard yields to the temptation to compute an empirical multiplier. He chooses the period from January 1934 through June 1936 because he believes that in that period there was little or no effective inducement for private investment, ignores the "hang-over" effect of government expenditures made in 1932-33, compares the excess of income in the second quarter of 1936 over the last quarter of 1933 with the quarterly average income-creating government expenditures of the period, and so deduces a multiplier above 6.[3]

Although Villard sees the uncertainties involved in such calculations, he seems to overrate the significance of this particular computation. He says (p. 361) that although we cannot be sure that there were neither indirect effects nor independent changes in other factors during this period, the calculation indicates that the increase in national income following 1934 "was not inconsistent with a multiplier as high as 6." This, of course, is true, but it is not clear that it was inconsistent with any other multiplier that might be suggested. In the next sentence the author's modest appraisal grows into the following claim: "Thus we know that it is possible for deficit spending to have a multiplier as high as 6, given the proper conditions, which shows that the theoretical work on the subject has not overestimated the possibilities of deficit spending." In other words, because it is possible for all factors combined

[2] One minor difficulty seems to have been generally overlooked. The general income velocity of money is computed by comparing income with the total supply of money, including that which is in capital balances. The income velocity that is needed for the purpose of calculating the multiplier is the velocity of that part of the new money which does not leak into capital balances. The income period relevant to the multiplier calculation is therefore shorter than the general income period. Except for very high leakages, however, the difference is not so great as that which J. M. Clark suggests on other grounds, namely, 2 months as against 4. Villard's criticism of Clark (pp. 151-53) seems to be sound.

[3] Villard does not explain why he compares the rate of income flow at the beginning of the period with the rate at the end, instead of cumulating additions to income for the whole period to get the product which corresponds to the definition of the multiplier. The two methods would give the same result if expenditures were steady and the multiplier were stable. In fact, however, the multiplier computed in this way is highly unstable. If we cut off the period at the end of 27 months instead of 30, we get a multiplier below 3. Cumulation of total income also gives a multiplier of about 3 (keeping Villard's simplification of substituting average for actual quarterly expenditure).

to increase the national income over an indefinite period of time by 6 times the amount of the deficit, we know it is possible for deficit spending alone to produce the same effect!

Villard, Hansen, and all the authors whose work is discussed by Villard compute multipliers on the assumption that leakages are permanent. In fact, however, leakage is in general simply the postponement of expenditure. The accumulation of a capital balance, whether by saving or by liquidating capital assets, does not imply a decision to hoard funds forever. What is involved is not a simple leakage ratio, but a schedule of the rate of leakage and the rate at which the funds that have leaked return to circulation. With any rate of leakage above zero, the capital balance accumulated from the leakage approaches 100 per cent as the rate of secondary expenditure approaches zero; but if there is any return flow out of the capital balance it will grow larger as the capital balance increases, and a point will be reached at which the return flow exceeds the leakage from the diminished secondary expenditure. The expenditures series, therefore, will not approach zero as a limit, but a perpetual cycle of rising and falling secondary expenditures will appear. Hence the value of the multiplier will always be infinity, even if leakage is 100 per cent, unless the return flow is zero.

Secular stagnation.—The most important issue raised by Hansen and Villard is the doctrine of secular stagnation, which is accepted by both authors as a proven thesis. The case for permanent deficit spending, or government spending financed by non-income-reducing taxation, stands or falls with this doctrine. If, for more than transient reasons, uninvested savings accumulate because there are not enough outlets for them (in the form of new investments that are likely to yield enough net income to make investment worth while), public policy must be directed either to discouraging saving or to supplementing income. On the other hand, if genuine investment opportunities, comparable to those which absorbed the enormous investments of the nineteenth and early twentieth centuries, are being neglected chiefly because entrepreneurs and savers now prefer the safety of capital balances to the possible gains of investment, research should seek to explain the decay of the propensity to invest, and public policy should be directed to encouraging the expansion of private investment.

Though for the moment obscured by the urgent problems of national defense, the issue is of paramount importance in planning for the postwar era. The quest of private profit through the investment of private savings gave us, in four generations, the greatest increase in mass standards of living that has occurred in the world's history; before we relinquish the hope of revival and further progress along these lines, and create the appropriate institutions for a society that cannot find uses

for its savings, the facts should be made perfectly clear. Particularly it should be clear that the failure of private investment to absorb savings in sufficient volume to maintain income is a result of technological factors, population changes, or other conditions outside the realm of public policy.

In my judgment the arguments advanced by adherents of the doctrine of secular stagnation are not strong enough to justify its acceptance as a basis of public policy. Some of the reasons for my skepticism may be summarized as follows:

1. If at a given time new investment is being held down by the lack of investment opportunities, existing profitable investments would be expected to command an unusually high price. The prices of stocks would be high and the yield of bonds would be low. The relative valuation placed by the market on very safe securities and risky ones, however, would be the same as in periods of high investment activity. In fact, this was not true during the depression of the thirties. Like other prolonged depressions, this was a period when the yield of very safe securities tended to be low and the risk premium tended to be high.

2. If the doctrine of secular stagnation were true it should be evidenced by keen competition for such new opportunities as do appear. Such inventions as are made should find backers more readily than in prosperity eras. In fact, the opposite was true throughout the "stagnation era," as in previous long depressions.

3. We should expect to find the transition from a period of abundant investment opportunity to one of inadequate outlets to be gradual. In fact we passed abruptly from the new era of perpetual prosperity to the new era of perpetual stagnation.

4. It must be remembered that the only "opportunities" that are ever conspicuous, or even certain, are those that have been seized upon. Had investors in the past refused to take the risk of building railroads, we should not know now that this opportunity existed all through the past century.

5. The explanations currently advanced to explain the inadequacy of investment outlets do not seem adequate. Hansen points out that of the three great historical outlets for savings—population growth, territorial expansion, and technological advance—only the third can be counted on in the future. He underestimates, I think, the importance of a fourth field, namely, the multiplication of equipment of types already known. Without any new invention whatever, the output of almost every factory and farm could be greatly expanded if capital were available to equip the average unit as well as the best are already equipped. A drainage ditch is not a new invention, but thousands of farms are inadequately drained. In the past the competition for capital arising

from the new opportunities has always prevented the complete utilization of techniques that were already common knowledge. Until the slackening of demand for extensive investment has made it possible to equip all industry so fully that every worker's output is the maximum that is technically feasible, we shall still have outlets for investment.

6. The decline of population growth means that less capital need be absorbed in maintaining the existing standard of living, but it also means that the possibilities of raising the standard of living are so much the greater, and the quest of higher standards does not seem to have lost its urgency. To provide one additional room for every family in the course of a decade would require far more investment in housing than is rendered unnecessary by failure to maintain our previous rate of population growth.

7. In fact, the technical situation in the housing field, viewed as an outlet for investment, has changed for the better in the last ten years, quite apart from the accumulation of a backlog through the slackening of building activity. Obsolescence of houses has gone on more rapidly in the last decade than at any time in the preceding half century. Air-conditioning, insulation, multiple baths, and built-in equipment constitute felt wants; the difficulty in supplying them is not on the demand side, except as demand is controlled by the shrinkage of income which is the result of the impairment of investment. At the same time, the development of automobile transportation has created opportunities for relocating the population and these opportunities have hardly been scratched.[4]

Finally, there is the question whether other conditions outside the hypothesis under review furnish an equally reasonable explanation of the slowness and weakness of the revival of investment after the recession of 1929-32. The only rival theory which it seems worth while to discuss relates to the changed impact of governmental regulation upon the inducement to invest—including under this caption taxation, wage policy and labor relations, price and rate controls, and supervision of the markets for money and capital. Of these, the most important are the two first mentioned.

[4] Villard comments (p. 344 footnote) that inventions likely to be exploited soon appear to involve expansion at the expense of existing industries; for instance, television or cheap airplanes would involve expansion at the expense of the motion picture and automobile industries. This, of course has always been true. The railroad and the automobile expanded at the expense of the stage coach and the horse and buggy; kerosene expanded at the expense of tallow candles and illuminating gas at the expense of kerosene and electricity at the expense of illuminating gas. All this is irrelevant. Investment in a new industry has never been retarded seriously by investors' concern over the fate of obsolescent industries. The destruction of capital values in old industries does not contract the flow of income to offset the expansion caused by the building of new industries.

The convincingness of a theory of politically-induced stagnation rests largely upon the fact that a pronounced change of governmental policy coincides neatly with the appearance of the phenomenon which we are trying to explain. The recession of 1929-32 was very severe, but if recovery had been equally rapid the accepted explanations would run in terms of business cycle theory rather than economic maturity. The slowness of recovery and the abortive character of the upswing of 1936, though they do find parallels in nineteenth century history, are sufficiently out of line with the usual business cycle sequences to make students look beyond business cycle theory for the explanation. But this is just the period in which public policy (unquestionably controlled by democratic processes) has for the first time in our history been expressed in a consistent series of policies that are unfavorable to investment.

This is not a blanket description of all New Deal policies. The bank rehabilitation policy, the program of direct loans to industry, and probably the unbalancing of the budget and the devaluation of the dollar were favorable to investment, and the N.R.A. was intended to be so. But after 1934, and especially after the failure of the "planned" recovery of 1936, public policy has evidenced more concern for social reform, regardless of its effects on recovery, than for the promotion of recovery.

Historically, until recent years, government, though operating through democratic machinery, was in fact dominated, in its economic aspects, by the ideas of investors and entrepreneurs. The rising standard of living of the masses of the nineteenth century was not the direct result of governmental pressure in the direction of higher mass incomes; it was the indirect result of the prosperity of business interests which were compelled by competition rather than by government action to share the fruits of progress with the remainder of the population.

In recent years, on the other hand, economic legislation has been the expression of a strengthened equalitarianism which seeks at the same time to push up the incomes of the masses by direct action and to cut down the incomes of the wealthy. For the first purpose the chief interest is labor policy; for the second purpose it is tax policy. The surtaxes on large incomes, even before the inception of the defense program, coupled with a failure to provide a system of averaging incomes, destroyed most of the incentive for the wealthy to invest in any but the safest securities. Discriminatory taxation on corporations cut heavily into another source of equity capital. At the same time, wage and labor policies were exerting steady upward pressure on costs.[5] In short, in a

[5] Hansen, in common with many others, argues (pp. 334-35) that when a wage reduction cuts down cost it equally reduces demand. This would be true only on the

period when we have had a deficiency of employment offers and a superabundance of would-be employees, we have tried to correct the balance by making the position of the employee more attractive and that of the employer less attractive. We depend on the profit motive to call forth a supply of investment, risk-taking, and employment opportunities, but direct our national policy to minimizing the share of profits in the national income. We depend on the minority of large incomes to provide the initiative and bear the risks incident to economic progress, but we strive to eliminate those inequalities.

This is not to say that the policies enumerated are necessarily unwise. They have advantages to offset against the disadvantages noted. If, as seems to be the case, we are deciding to commit an ever-increasing proportion of economic responsibility to political rather than to business leadership, economic life can go on under techniques of control that will be developed in line with the new ideals. My point merely is that a propensity of the capitalists to seek safety rather than profit, to shirk the responsibilities of investment, is a natural consequence of governmental policies which are inappropriate to an economic order controlled chiefly by private initiative under the profit motive.

---

assumption that profits are never spent by the recipients. It is not sufficient to show that wages are likely to be respent more rapidly than profits. Unless all of an increase of wages is a net addition to demand, industry as a whole can recover from the enhancement of buying power only part of its added costs; the balance must come out of profits. This is of no great importance in a period of expansion and rising profits, but in a period when the problem is to maintain investment, a wage increase forced by governmental or trade union action must be counted a retarding factor.

COMMUNICATIONS

Rebuttal to Professor Crum and Mr. Musgrave

In the September, 1939, issue of this *Review* appeared two articles in reply to my article in the March, 1939, issue entitled, "The Double Taxation of Savings."[1] One of these replies was by Professor W. L. Crum of Harvard University and was entitled, "On the Alleged Double Taxation of Savings."[2] The other was by Mr. Richard A. Musgrave, also of Harvard, and was entitled, "A Further Note on the Double Taxation of Savings."[3]

In my article, as elsewhere, I have contended, as did John Stuart Mill, Alfred Marshall, A. C. Pigou, Einaudi, and others, that to tax savings and then to tax the fruit of those savings is virtually to tax the same thing twice. It is taxing not only the fruit but also the tree which bears the fruit, the tree being of no value except as it bears the fruit.

For purposes of illustration the simplest case is that type of saving which is invested in a perpetual annuity. Under an income tax which treats savings as income, a 50 per cent tax on the saving reduces by 50 per cent the subsequent fruit of that saving and then in the subsequent years, it takes 50 per cent of the remaining fruit, making actually 75 per cent in all, instead of the nominal 50 per cent. In like manner, a tax of nominally 10 per cent amounts actually to a 19 per cent tax, and a nominal 1 per cent tax comes to a shade under 2 per cent, whereas, in the case of a person who neither saves nor dissaves, 50 per cent is actually 50 per cent, 10 per cent is 10 per cent and 1 per cent is 1 per cent.

As to the strict mathematics of this, including less simple cases, these have been covered in the earlier writings to which I referred the reader in the article criticized by Professor Crum and Mr. Musgrave.

In the March, 1939, article I also suggested, as a merely incidental phenomenon, that a saver might be tempted to migrate from a state where spendings-plus-savings are taxed to a state where only spendings are taxed; and that a dissaver might be tempted to migrate in the opposite direction: from a state where his actual spendings are taxed to a state where spendings-minus-dissavings are taxed; and that people who neither save nor dissave would have no preference as between the two states, other things being equal.

But my basic comparison was between the saver and dissaver in one and the same jurisdiction—a jurisdiction which taxes spendings-plus-savings; whereas Mr. Crum's comparison is basically (though with variations) between savers in one state and savers in another state, the two states having equal budgets, equal savings, and equal spendings, but one of the states taxing only spendings and the other taxing spendings-plus-savings (with almost no men-

[1] *Am. Econ. Rev.*, vol. xxix, March, 1939, pp. 16-33.

[3] *Ibid.*, Sept., 1939, pp. 549-50.

tion of dissavings). And Crum reaches the conclusion (to which I offer no objection) that the taxing authority which did not tax savings would, in order to meet its budget, have to make up for the exemption of those savings.

Even if we concede this and other conclusions of Mr. Crum (under his very unrealistic assumptions), there is practically nothing in his article on the question supposed to be at issue—the existence of double taxation when savings are taxed.

In fact, if Professor Crum's article did not purport to have reference to mine, I could criticize it very little. And if his references to mine were entirely correct, I would even say his article *confirmed* mine. For the only part of his discussion which is very germane is included in the three pages, 545-47, where he shows correctly that the *savers* in B-land (where savings are exempt) do have an advantage over the *savers* in A-land, where savings are taxed, and that national saving might even be "encouraged" by the B tax system.

Yet he seems to think that his comparisons disprove double taxation. On page 544 he asks: "Where then is B's advantage over A? And is A a victim of 'double' taxation?" And he repeats these questions on page 547.

He evidently asks these rhetorical questions because his numerical illustration shows that the *average* A (inhabitant of the state where savings are taxed) and the *average* B (inhabitant of the state where savings are not taxed) will fare alike—that the *average* A has no "advantage" such as Professor Crum thinks I claimed. And he is, I agree, correct—at least under his assumptions.

He quotes my assertion that "There is mathematical proof—proof that if savings are taxed as income and later the income from these savings is also taxed, there will result a subtle form of 'double taxation' "; but in denying that I had proved this (pp. 538 and 547), he apparently had sole reference to the arithmetical illustrations in the March, 1939, article and did not notice the footnote explaining that "Proof of double taxation was offered in *The Nature of Capital and Income,* especially in graphic form, and again in *Econometrica* (January, 1937, 'Income in Theory and Income Taxation in Practice'), in algebraic form" and that I merely added, "The present article [March, 1939] furnishes some new arithmetical illustrations."

There are several other respects in which a reader of Professor Crum's article will fail to get a true picture of the proposals which he criticizes.

It would seem that (if he had noticed the fact) he would have told his readers that I do favor quite strongly one form of double taxation, namely, the taxation of big accumulations at the death of the accumulator plus the taxation, later, of the income from those accumulations as spent by the heirs.

I said: "So far as taxation is concerned, the best method for preventing an undemocratic and hereditary plutocracy, I believe, would be through estate and inheritance taxes. An inheritance tax is a tax frankly on capital value, which means a pre-tax on future income and so implies a second tax when that future income arrives. This species of tax on capital, coming at the time when the property passes at death, seems to the present writer more easily justified than any other tax on capital in an ostensible income tax" (p. 32).

On the question of expediency as between the two sorts of income tax, the main comparison must, of course, be between the two regimes—a spendings tax vs. a spendings-plus-savings tax—in one and the same jurisdiction, say the United States, regardless of the incidental question of migration.

Professor Crum's comments apply to a comparison between the two jurisdictions, especially when he complains that "Z [his chief saver in the jurisdiction which exempts savings] waxes ever fatter," and then asks, "What are the consequences to Z? First is the political fact that, even if X and Y—the majority of the population in a nation [B] which presumably professes to enjoy democratic government—consented to the arrangement in Year O and for some years thereafter, the worm would turn; and Z would sooner or later be taxed in deadly earnest on his 'extra' savings or the 'yield' thereof or both" (p. 547).

But, under the regime proposed by me, the savings *would* be taxed—as an estate. And (with realistic assumptions) the tax revenue would be greater than under the regime favored by Crum.

This last consideration (of greater revenue) I did not discuss in the March 1939 article, and it needs only a passing reference here.[4]

The important element in a nation's savings or capital-increase comes with new inventions. Such examples of capital-increases grow fast from year to year like compound interest, that is, *if they are tax-exempt*. A tax on the capital-increases would forestall this rapid growth. Thus, one important consequence of this spendings-plus-savings tax is that it produces far less revenue than would the spendings tax, especially under conditions resembling the actual world more closely than the conditions assumed in Professor Crum's highly hypothetical communities.

One of Professor Crum's most theoretical and least realistic assumptions is a 5 per cent interest and capital-increase rate uniform for all individuals and for the government, whereas the facts of life are far different. In real life the rate of interest at which the government can borrow is *below* other rates and the rate at which private initiative increases our national wealth is, in those cases which contribute most, far *above* the rate under government management. Under these real life conditions the revenue received by the government from taxing savings would *not* be used as productively as it would be if left in private hands. Our capital equipment has been built largely from new inventions, privately developed, with annual increments of capital value far in excess of the market rate of interest; while our governmental investments have usually been wasteful.

As I go over Mr. Crum's article for the third time, I find that my only really serious dissent from his views, as I understand them, is felt when he pictures the savers' savings as being made at the expense of non-savers.

My own picture is altogether different. I regard the typical capital-creator as one who develops new inventions like the railway, automobile, radio and movie, which are typically far more beneficial to others than they are to those who, through developing them, become the owners of huge aggregations of capital in the form of productive plants. These accumulators—the Vander-

[4] For a discussion of this point, see "A Second Reason for Not Taxing Savings," *Taxes*, Aug., 1941.

bilts, Rockefellers, Fords—seem to me, in the first generation, to function more as national benefactors than as beneficiaries. Only when, as often happens in subsequent generations, the heirs become primarily spenders, instead of savers, do I think of the owners as self-indulgent or parasitical. Accordingly, I would encourage savings and discourage spendings, whereas the tax on savings doubly taxes the saver and doubly exempts the spender, thus going directly contrary, in both cases, to sound public policy.[5]

But, as to any substantial issue between Crum's article and mine, I can find no such issue, only an "alleged" issue.

Between Mr. Musgrave and myself there is more of an issue, though not very serious. Mr. Musgrave says: "The point of issue is whether the general income tax [*i.e.*, one on spendings-plus-savings] involves a hidden discrimination against income from saving or whether, on the contrary, Professor Fisher's spending tax results in an analogous discrimination in favor of saved incomes" (p. 549). And he concludes that: "From a logical point of view Professor Fisher's statement that the income tax discriminates against savings is no more valid than the opposite contention that the spending tax discriminates against spending" (p. 550).

This, it seems to me, is carrying relativity too far. Or is it not far enough? It is true that if any tax system A hits the saver harder, *relatively* to the spender, than does tax system B, it logically follows that tax system B must hit the spender harder *relatively* to the saver than does tax system A. That is self-evident enough. But it misses the point. The comparison, to be meaningful, must not be merely between two things. Both things must be relative to a third as a common measure. That third thing is discounting or capitalization. It is based on the fact that the tree derives its value from the fruit.

At the very start Mr. Musgrave seems to me to go off the track when he says: "Notwithstanding the merits of Professor Fisher's income concept [*i.e.*, yield (which is equal to spendings)] for purposes of general theory, we find no necessity to use the same income-concept for all purposes" (p. 550).

I am quite ready to agree that there is no such necessity "for *all* purposes." But I cannot agree when Mr. Musgrave concludes that the yield concept is not germane to the purpose of taxing income.

In at least two important respects concerning "general theory," the yield concept is more applicable to income taxation than is any other income concept: it would make the tax on income a tax on *real* income; consumption, and the capitalization or discount principle, would make it in tune with the principle underlying market values.

To compare two streams of income (in the yield sense), we discount them. And to compare two streams of taxes paid out of those two streams of income, we also discount. Such comparison of the two income streams is exemplified by the market-values of the income-bearers, such as shares of stock; and comparison of the two tax-streams is exemplified when the taxes are supposed to be "compounded" for or prepaid in spot cash. These com-

[5] This subject and others related to it are elaborated in "A Second Reason for Not Taxing Savings," *Taxes*, Aug., 1941; they will be treated mathematically, in the January *Econometrica*; and the whole problem of income tax reform will be the subject of a forthcoming book by myself.

parisons—between the incomes taxed and between the taxes thereon—will run parallel if we use the yield-concept of income (which I prefer for tax purposes). But they do not run parallel if we use yield-plus-savings concept of income (which Mr. Musgrave prefers for tax purposes). For a tax on the savings ingredient (or capital-increase) *distorts* the parallelism. When such capital-increase is taxed (or capital-decrease is deducted), a discount comparison between the taxes is entirely out of tune with the discount comparison between the incomes.

For instance, consider two perpetual annuities, *m* and *n*, each earning at first $5.00 a year and each having a market value of $100, the "basis" being 5 per cent. Suppose that in the case of *m* there are no savings, but that in the case of *n* the first $5.00 earned is saved and reinvested on the same (5 per cent) basis, adding 25 cents a year to the income and, in effect, transforming this *n* annuity into an annuity, not of $5.00 a year, but of $5.25 a year, and not beginning at once like annuity *m* but being deferred one year.

Thus transformed, annuity *n* actually *yields* nothing the first year though it *earns* $5.00. Its market value is still $100[6]; for the market value is always discounted *yield,* not discounted *earnings.*

Now suppose a 20 per cent tax on the two incomes, *m* and *n*. This would, from the start, take $1.00 a year out of the unchanged annuity *m* (of $5.00 a year). The present value of said $1.00 perpetually is $20. That is, this $20 could theoretically be paid in spot cash in order to "compound" for the $1.00 a year.

But as to *n*—which has been transformed (by saving $5.00 the first year) into an annuity of $5.25 a year beginning one year hence—the 20 per cent tax will be different, according to which income concept is used for the tax base. That is, if "income" is taken to mean *yield,* the 20 per cent tax is zero the first year and $1.05 every year after, and this series has a present worth of $20.[7] Thus both annuities are worth $100 and both tax series are worth $20, or 20 per cent of the original $100 market values. These two values and the two taxes run parallel; whereas, no such parallelism applies if the taxable "income" is taken to mean "earnings" so as to include the $5.00 earned the first year but not spent. If that $5.00 is taxed the first year, at 20 per cent, $1.00 is taken, leaving $4.00 out of the $5.00 of savings, so that a year hence the capital is $104. This will thereafter yield $5.20 a year. A 20 per cent tax on this is $1.04 a year in perpetuity. Thus, the present value of the whole tax series, including the $1.00 the first year, is not $20 but $21.80, which is *more* than 20 per cent of the original $100 market value.

There is therefore a "discrimination" measured by $1.80 against the saver. Though his property has the same value ($100) as the spender's, his tax burden is heavier *measured in present value,* which is the only available measure when time shapes differ.

This same principle applies in the case of investment followed by disinvest-

[6] One way to compute the market value of *n* on a 5 per cent basis is in two steps as follows: the income of $5.25 a year, beginning one year hence, is 5 per cent on a capital value of $105 one year hence, which $105 is, in turn, discounted, $100 today.

[7] *I.e.,* $21 one year hence, worth $20 today.

ment and the spending of the saved sum, say two years later. If that sum is taxed when received, there is double taxation. It is not a mere "difference in timing" as Mr. Musgrave seems to think. Mr. Musgrave himself virtually concedes more than a difference in timing when he uses the words "bear harder" (p. 550). He says: "If the original income is invested, a given percentage tax on income will, over the period from income-receipt to disinvestment, *bear harder* (italics mine) on the 'saver' than a tax payable at the time of disinvestment, yielding the same amount. The cause of the excess burden on the saver lies in his loss of interest . . ." (p. 550).

Thus there is always *some* double taxation whether the consumption is put off two years, fifteen years, or forever. In all cases there is a twofold tax, namely, a tax on interest, the fruit of savings, and a tax on the discounted value of the said interest.

When, therefore, Mr. Musgrave says "the original income [saved] is thus taxed but once, whether or not consumption has been delayed" (p. 549), he overlooks some of the rôle played by interest. In the example he has chosen (of a two-year interval), this oversight is not serious. With a two-year interval only $9.29 out of the original $100 saved is taxed twice, this $9.29 being the discounted value of the two years' interest items of $5.00 each. The remaining $90.71 "is taxed but once." But the interest becomes a more and more serious factor the longer "consumption has been delayed."

It is entirely misleading to contrast as equivalents the $100 saved today and the $100 spent (plus interest) two years later. These two $100's are *equal* numerically but by no means *equivalent* at any given instant. The equivalent (at the start) of the later $100 is only $90.71 out of the earlier $100.

Like Mr. Crum and a number of other writers, Mr. Musgrave takes for granted that "A given percentage tax on all income [in which he includes savings] will yield more revenue . . . than a similar percentage tax on incomes after the deduction of savings" (p. 549). He says that, if savings are included in taxable income, we have "a broader income tax base" (p. 549) and that, if savings are excluded, the "range of income tax brackets would be narrowed enormously" (p. 550).

Evidently he has not fully worked this out with figures. For, in the end, the exact opposite is typically true. Paradoxically more taxes can, in typical cases of new inventions, be obtained from the "part" excluding savings than from the "whole" including savings.

One example must suffice here. Suppose someone like Henry Ford was worth $1,000 in 1900 and increased his net worth by 40 per cent per annum until 1940. He would then be worth $700,500,000.

Suppose this growth occurred without any tax on his capital-increase. Then contrast the results, as given above, with what would happen under a tax on capital-increase such as Mr. Musgrave favors. Let that tax be only 20 per cent. The capital in 1940 would then be not $700,500,000 but only $66,500,000. That is, the 20 per cent tax would destroy over 90 per cent of the capital!

Moreover, the tax revenue for the 40 years would be only $16,600,000

whereas, if there had been no such tax killing the goose which ought to lay the golden egg, a tax *of merely 3 per cent* would, at the end, mean $21,000,000.

Mr. Musgrave alludes to "a growing group of economists" (p. 550) favoring, so he seems to think, a general tax on savings. If there be such a group, it is probably owing to a misunderstanding of Keynes (who is now, on the contrary, proposing compulsory savings), and the group does not seem likely to keep on "growing." On the contrary, the spendings and destructions of capital, public and private, in the past decade, must (I, for one, feel sure) soon bring about a reaction toward a renewed and keener appreciation of the value of normal savings.

The idea stressed by Musgrave that "saving" does not necessarily imply "investment" is important under certain circumstances, notably during deflation when there is hoarding or during the New-Deal hounding of business. But these circumstances do not invalidate the fundamental double taxation which is the target at which both Crum and Musgrave aimed. Nor do I see any ground for fearing that the exemption of savings would encourage hoarding *more* than investing!

I freely admit that "policy considerations" (p. 549) may sometimes afford extenuation or even justification for double taxation. But to justify double taxation (when it can be justified) is quite different from contending, as Mr. Musgrave does, that "no double taxation prevails" (p. 549).

IRVING FISHER

New Haven

Proposal for Cushioning the Transition to a Peacetime Economy

I

In considering the means for preventing a possible depression in the post-war period, it is useful to distinguish three different types of causal factors which may give rise to the unemployment of human and material resources. These are: (1) Sudden cessation of the demand for military products; (2) dislocation of trade caused directly and indirectly by the war, such as the loss of foreign markets, the distortion or restriction of international capital movements, etc.; (3) secular, political, or institutional factors which were present in the economy before the war and which re-assert themselves (in more or less modified form) after its cessation.

These three classes of potential causes of post-war unemployment are, of course, closely interrelated, each tending to reinforce the others. The advantage of considering them separately lies in the fact that a remedy appropriate to one of them will not necessarily be appropriate to the others.

Proposals so far advanced for dealing with the post-war problem for the most part envisage large scale public works of various kinds, the expansion of social security programs, governmental action looking toward the revival of international trade, etc. These programs, necessary and proper though they

may be, are not directed specifically at the unemployment springing immediately from the cessation of the war. They expressly or implicitly assume that the other elements making for depression in the post-war world; *i.e.*, those covered by (2) and (3) above, are more fundamental than this factor. This may very well be true. Yet the prevention or mitigation of unemployment resulting from the disappearance of military demand as such is highly important, not only for its own sake but also, as already suggested, because such unemployment would tend to intensify other unfavorable post-war influences. It is this—the transition problem proper—to which this paper is devoted.

The problem divides itself into two parts: (1) the transfer of resources from the production of war goods to the production of peace goods and (2) the "secondary deflation" effects following upon the interruption to full employment. In view of the memory of the extraordinarily deep depression which preceded the war, cumulative "secondary" effects, induced by hoarding and retrenchment, are likely to prove far more serious than the mere problem of physical readjustment and transfer.[1]

One method which suggests itself for heading off unemployment in the immediate post-war period is the accumulation, during the war, of *a backlog of orders for civilian goods,* especially for the durable consumers' goods the production of which was most interfered with by the war. Not only would such a backlog provide immediate employment in the industries concerned but, perhaps even more important, it would help to maintain "confidence" in other areas of the economy.

The paragraphs that follow outline a proposal which, in the writer's opinion, offers a distinct possibility for building up the type of backlog described.

II

The central objective of the plan is to build up a large volume of private savings which may be counted upon to be spent shortly after the cessation of hostilities and which will be accumulated for that special purpose. This is to be accomplished through the issuance by the United States Treasury of a new type of bond.[2] This bond (1) shall bear a high rate of interest, perhaps between 4 and 5 per cent; (2) shall be payable only to recognized sellers of specified goods in full or partial settlement of post-war purchases made by the bondholders.

The commodities in payment of which the bonds will be honored will include all the more important durable consumers' goods: farm machinery and equipment; residential or business buildings; and "capital goods" in general. The articles purchased must be new, not second-hand.

[1] In a historical study of the relation of war to the business cycle, it was found that "When the war is terminated, a recession occurs in the belligerent countries. . . . [This] is soon followed by revival and prosperity." E. M. Bernstein, "War and Business Cycles," *Am. Econ. Rev.*, vol. xxx, Sept., 1940, pp. 530-31. For the reasons stated above and also because of the rigidity existing in today's economic structure, there is much more likelihood that a recession after this war will develop into a major depression than was the case in past wars.

[2] If it is felt that the multiplicity of types of bonds may be confusing to the public, the instruments could be called Merchandise Saving Certificates, or by some similar name.

The bonds, which may be transferable, shall have no maturity date but shall be payable on or after a day proclaimed in advance by the President. This date will be the earliest on which, in the President's judgment, substantial deliveries of one or more of the specified goods can be begun. (For convenience, this date will be referred to below as X Day.) On or after X Day bondholders may receive payment by endorsing their bonds in full or partial payment of a new purchase of any of the specified goods, but in no other way. Purchases on which the bonds will constitute at least a one-third payment shall be exempt from all war excise taxes in force at the time of purchase. (Manufacturers would obtain refund of the tax by furnishing proof of sale of the article to a retail customer.)

In order to discourage retention of the bonds after X Day all interest and tax exemption shall cease six months after X Day (or as of the date—subsequent to X Day—of endorsement of any bond to a dealer, whichever is earlier). However, in view of the possibility of a situation arising (as it did in 1919) in which demand in a great number of lines may outrun supply, this provision should be flexible. It could perhaps give the President a range of time, such as between three months and two years after X Day within which interest on the bonds and tax exemption might be discontinued.

Upon turning in a bond to a dealer the customer will be entitled to receive credit for all interest due on the bond. In order to facilitate the transaction each bond will carry a table showing the amount of interest due after stated intervals. In cashing the bonds, dealers will be required to furnish proof of sale of a new article and of the date of the transaction. The bonds will be available in denominations as low as $25, with installment purchases made possible through stamp books.

Any holder may receive cash for his bond at any time before the day of the President's proclamation (see below), but if he avails himself of this privilege shall forfeit all interest.[3] The privilege of converting bonds into cash shall end on the date when the President proclaims X Day (which date will, of course, precede X Day).[4] However, to take care of cases where a small surplus is left after any desired article is paid for in full, bonds or stamps up to $25 value in such cases will be redeemed in cash after X Day.

The Treasury shall have the right to suspend (and resume) the sale of the bonds at any time, and to call in outstanding bonds after two years subsequent to the date the first bonds were issued.

III

It will be seen that the above scheme, if successfully carried through, will serve a double purpose: (1) it will absorb purchasing power during the war; (2) at the end of the war it will *convert the purchasing power into actual purchases.*

It is the latter characteristic of the plan which distinguishes it from pro-

[3] An exception to this penalty would be made in case of the death of the bondholder.

[4] Thus between the day of the President's proclamation and X Day, a period which might perhaps be 90 days, the bondholders' funds would be "frozen," being repayable neither in cash nor in goods.

posals which look forward merely to making purchasing power *available* in the post-war period without guaranteeing its actual use in creating demand. Furthermore, it should be noted that the plan will create a direct demand for employment in that sector of the economy where employment will be most urgently needed, namely, in the so-called "hard" goods industries.[5]

It may be argued here that these purposes would be accomplished as well by the "Keynes plan" of compulsory saving as by the scheme presented above. Since the "forced savings" would in general be disbursed to individuals in the lower income groups with a high propensity to consume, they would in all likelihood soon be spent. This argument deserves some consideration.

Let us assume first that the savings are paid out as a lump sum. If so, there is no presumption whatever that the use of the money will conform to the usual income expenditure pattern of the individual. On the contrary, these extraordinary receipts would probably be regarded as capital gains. Much of the money would be saved and the fraction spent on consumption would be smaller than the corresponding fraction out of ordinary income.

Now let us suppose that the payment of the savings money is spread out in weekly payments over a period of time. If the recipient is working, this money will constitute an addition to his income. But it would be a mistake to apply the individual's ordinary marginal propensity to consume to this added income, for it is purely temporary and the recipient knows that it is. It is altogether reasonable to assume that he will spend a smaller fraction of it than if he considered it to be permanent.

Moreover, we know that, in any event, not all the "forced savings" receipts, nor even a large part of them, will be spent on durable consumers' goods. This is true *a fortiori* if the individual is unemployed. Yet it is precisely in the "hard" goods industries that unemployment will make itself felt most quickly and severely, with deleterious cumulative effects on the rest of the economy.

It should be clear, therefore, that as far as assuring expenditure of money saved during the emergency is concerned, the Keynes plan does not take the place of the scheme here presented. Much of the above argument could be repeated with respect to unemployment benefits, separation wages and the like. Furthermore, the experience of the depression has amply demonstrated that the "secondary" effects of such expenditures cannot be compared to the like effects of the expenditure of wages earned in private industry.[6]

The appeal to the American public to invest in the bonds would be based

[5] A scheme under which the government borrows money on condition that the repaid funds must be spent only in a specified way may seem fantastically new, but has a precedent. This precedent is to be found in the German government's *Volkswagen* campaign under which the Labor Front collected weekly contributions from German citizens as payments on popular-priced automobiles which were to be delivered at some time in the future.

Another analogue is the provision in the latest British tax bill whereby a certain percentage of the excess profits tax will be returned to the taxpayer after the war on condition that he spend it for reconstruction purposes. *Cf. The Economist,* April 12, 1941, p. 475.

[6] These facts by themselves are of course no argument against these schemes as anti-inflationary devices.

primarily on grounds of self-interest. The greatest incentives that would be counted on to sell the bonds would be (1) the high rate of return, and (2) exemption from the high war excise taxes.

Furthermore, purchase of the bonds could be held out as a plan for acquiring some definite article in which the individual is interested. It would be a way of "saving up" to get a car, or a washer, or a refrigerator. People who will not save "in general" may, with the proper approach, be induced to save for a special purpose.[7] This appeal should be especially strong at a time when most durable consumer goods are scarce. Finally, with a little imagination, a powerful appeal to buy the bonds can be based on the essential purpose of the plan, namely, to maintain employment after the war.

The cost of the plan would be very moderate. If the interest rate is 5 per cent and the amount of bonds sold (uniformly) over a three-year period, and outstanding at the end of that time, is 10 billion dollars, the *gross* additional cost to the Treasury would be in the neighborhood of 400 million dollars.[8] The *net* cost will be much smaller because manifestly the higher national income brought about by the expenditure of the backlog[9] should greatly increase tax recoveries in the immediate post-war period.

IV

It is obvious that the success or failure of the scheme here presented depends almost entirely on whether the special kind of bond contemplated will find acceptance with the public. There appear to be no other problems, administrative or otherwise, of a major character.[10] It is therefore necessary to consider the factors which may militate against the sale of the bonds.

The first and perhaps most important of these is the natural reluctance of people to accept a limitation in advance on the manner in which they may spend their savings. The question may be asked: Why should people commit themselves to buy a durable good after the war when they know they may be out of work and lack the ordinary necessities of life? In answer to this question it may be admitted at once that the bonds will not compete—and are not intended to compete—with savings accumulated against unforeseen emergencies. They will appeal only to those who deliberately intend to use part of their income (or accumulated savings for that matter), to acquire some durable consumers' good.

These will include:

(1) those who would like to buy the commodity now but cannot do so because it is not available;

(2) those who have already made provision against a "rainy day" or

[7] This is borne out by the popularity of "Christmas Savings Clubs."

[8] This is based on an assumed cost to the Treasury of between 2 per cent and 2½ per cent for money from Defense Saving Bonds.

[9] The backlog, it should be noted, may be substantially greater than the amount of bonds outstanding, since many of the bonds will be used only as down-payments.

[10] Of course, the government will be faced with a major refinancing operation at the time of the payment of the bonds, but there will be no net increase in its debt.

have sufficient earning power to do so concurrently with investing in the bonds;

(3) those who had sufficient income to be able to afford the particular commodity (say, an automobile) before the war and make the not unreasonable assumption that they will be able to afford it afterward. (In view of the fact that the great majority of those now employed were employed before the war, this should be a very large category.)

Moreover, it should be remembered that the plan will offer the prospective bond purchaser the privilege of withdrawing his principal at any time.[11] This is a safety clause which should be very effective in overcoming sales resistance on this score.

The second factor which may impede the sale of the bonds is the uncertainty of the time of repayment. Many individuals may be willing to save for a year or two years with an intended purchase in mind, but may not be willing to make the time of their purchase contingent upon some eventuality the occurrence of which lies in the indefinite future. This is a valid objection, but it is offset, at least in part, by two considerations.

In the first place, there is the cancellation privilege mentioned above. A person may put his money into the bonds on the assumption that the war will be over in, say, two years. He need not hesitate to do this because if, after that time, the end is not yet in sight, he will be able to withdraw his money.

Secondly, most people who wish to acquire durable consumers' goods will not find it possible to satisfy their desires while the emergency lasts anyway. Hence, the actual choice that will confront them will be between saving their money until after the war and spending it on *other* goods or services now. If they decide to save, with the object of buying some durable after the war, they will be no worse off if they save by investing in the bonds than if they saved in any other form.

The enormous benefits to be gained from the success of the plan, coupled with the fact that practically nothing would be lost in the event of failure, argue strongly for making the experiment.

ALEX. ROSENSON

Washington, D.C.

Population Growth, Investment, and Economic Recovery

It has frequently been stated that the declining rate of population growth was one of the major contributing causes for the failure of the American economy to recover fully from the depression of the 1930's.[1] Since this view has not gone entirely unchallenged, it seems appropriate to examine a little more fully the effects upon the economy of a slowing down of the rate of population increase during a period of general underemployment. It is my contention that, during such a period, there is no important demonstrable

[11] Up to the time of the President's proclamation.

[1] For an expression of this view, see especially A. H. Hansen, "Economic Progress and Declining Population Growth," *Am. Econ. Rev.*, vol. xxix, March, 1939, pp. 1-15.

connection between the rate of population growth and the level of employment.

Population growth, it is claimed, might affect investment, and thus the level of employment, in two ways. It could increase the demand for investment either for the "widening of capital" or for the "deepening of capital." By definition, the "widening of capital" means investment to supply tools and equipment for additional workers who are increasing the total output of finished goods. Unless there first occur additional output and additional employment, there will be no demand for investment for the "widening of capital." The claim, therefore, that an increasing rate of population growth increases the demand for investment for this purpose involves the tacit assumption that employment has increased. Since the problem is to demonstrate that an increasing rate of population growth will raise the level of employment, we cannot make such an assumption.

The effect of population on the "deepening of capital" is a result of the rôle that the rate of population growth plays in determining the composition of the flow of final goods. The argument seems to be that a high birth rate so affects the individual family's pattern of expenditure that more is spent on goods requiring much investment. Among the poor, the group numerically largest and therefore the group in which a changing birth rate would have the most effect, there is an income level so low that almost the entire income must be spent on food, clothing, and shelter.[2] One more mouth to feed means just that and may not call for additional housing facilities and additional food but merely more crowding in the present rooms and more division of the present amount of food. Certainly there is no vast amount of income being spent in non-investment utilizing fields such as personal services which could be shifted to housing. This income group, then, will not by its consumption provide any great opportunities for investment because of a rising birth rate. In the wealthy population strata, the amount of automatic saving is sufficiently great, and the number of rich performing such saving sufficiently small, that the practical importance of any change in the birth rate of this group is likely to be rather negligible. In the middle-income group it is true that an increase in the birth rate will cause an actual change in expenditure away from other types of goods to food, clothing, and shelter. If these three are "the most highly capitalized goods in the economy,"[3] then it necessarily follows that there will be an increase in investment. We may, however, well question the actual importance of this factor during a depression period. An increase in the demand for housing might, in such a period, more largely take up the slack of vacant housing facilities rather than produce new investment and new construction. In addition there may be an appreciable loss of investment because of the shift of demand. For example, the family which is renting a larger house may be forced to retain its old automobile a year or two longer, or refrain from purchasing a second car. The production of automobiles is also capital using,

[2] At least this is likely to be the case during a period of general underemployment and certainly seems to have been true during the decade of the 1930's which we are considering.

[3] Both Hansen and Keynes feel this to be true of housing accommodations and agricultural products. See A. R. Sweezy, "Round Table on Population Problems," *Am. Econ. Rev.*, Suppl., vol. xxx, March, 1940, p. 397.

perhaps as much so as the production of housing accommodations. Thus the shift in consumer demand might cause no net increment in the demand for investment.

In short, it is impossible to answer in advance whether an increased birth rate would occasion a greater demand for investment to be used in the "deepening process" of capital formation. The discussion of the effect on the "deepening process" has been limited, heretofore, to an increasing rate of population growth occasioned by a higher birth rate. More definite comments can be made about an increment caused by immigration. An influx of immigrants can have no influence whatsoever on the "deepening of capital" resulting from changes in the character of the output as a whole since this group of the population does not shift its demand from one type of product to another type requiring more investment. It cannot *shift* its demand because the group had no effective demand before it entered the economy.[4] Thus immigration cannot increase the demand for investment through the "deepening of capital" process.

Much of the recent discussion of the secular stagnation hypothesis has considered the effect of the rate of population growth directly upon employment rather than upon investment. In an analysis of this effect, it is essential that confusion between total population and total *employed* population be avoided. An initial decline in total employed population will, through the operation of the multiplier effect, cause a further decrease in employment. This would be of relevance to an evaluation of the effects of a declining rate of population growth only if *total* population is the *working* population.. This, however, would mean the absence of unemployment and is, therefore, of no interest to the problem under consideration, the effects of a declining rate of population growth in a depression period.

Some of the writers on this subject have considered it obvious that an increasing rate of population growth "stirs up building activity" and increases the demand for consumers' goods.[5] Unless there is an increase in purchasing power first, there can be no increase in demand, only a shift of demand which may or may not be advantageous to employment. An increase in effective demand can result prior to new investment from three sources. The new population may obtain an income as a result of securing employment. This, of course, would increase demand but again the problem is to explain how they got jobs. The new population may, secondly, be granted governmental relief and so obtain purchasing power. Obviously this might increase effective demand, but it is only saying that the government may be able to stimulate employment by deficit-spending. It is the spending that matters in this case, not the population increase. The third possible source from which the increment of population might obtain purchasing power is from private charity. This may be a diversion of expenditure with the donors foregoing their own consumption in order to give to the new population, or forcing the prior recipients of their charity to divide the proceeds with the new population.

[4] Except, of course, for products previously exported.

[5] A. Lösch, "Population Cycles as a Cause of Business Cycles," *Quart. Jour. of Econ.*, Aug., 1937, p. 658.

The effect in both cases is indeterminate depending upon the actual shift of demand that occurs. Those supporting the new population may, however, do so by a reduction of their savings. This would raise the level of employment, but the population increase is only an initiating force causing charity to increase. If some other factor caused donors to be more charitable, the effect would be the same.

There is, however, another possibility which must be considered. If, because of an increasing rate of population growth, expectations of entrepreneurs change so that they now believe certain investments to be profitable, whereas before the population increase such investments were not deemed profitable, then obviously investment and employment will increase. One of the important determinants of the marginal efficiency of capital is the state of expectations of entrepreneurs. If entrepreneurs become more optimistic, then investment must increase; and, if an increasing rate of population growth makes entrepreneurs more optimistic, then an increasing rate is beneficial to employment.

It is probably true that, in a boom period of full employment, rapid expansion, and an increasing population, a sudden decrease in the rate of population growth would tend to make investors more cautious. Whether an increasing rate of growth would have beneficial psychological effects during periods of depression is another matter. Popular opinion seems to hold that an increasing rate of population growth will cause a larger absolute level of unemployment. There is during every depression a certain public clamor to restrict immigration and even to further emigration from the country. At the thought of additional refugees coming into this land, the cry arises that the refugees would take jobs away from Americans. Such a popular reaction to an increasing rate of population growth might influence entrepreneurs to be pessimistically inclined rather than optimistic as a result of the increase. Investors may feel that such an increase will cause more absolute unemployment and economic hardship in the country so that investment prospects are less profitable rather than more profitable.

The conclusion seems to follow that an increasing rate of population growth might actually raise the level of unemployment during a period of depression. This, at least, seems a truer picture of the situation than Professor Hansen's declaration that the declining rate of population growth was an independent, contributing factor for "sick recoveries which die in their infancy and depressions which feed on themselves" such as we experienced in the 1930's.

MARTIN M. ROSEN

Washington, D.C.

Who Pays for the Gold?

A correspondent sends in the following colloquy[1] between Representative F. C. Smith and the Under Secretary of the Treasury, thinking that such a

[1] *Congressional Record,* daily edition, Nov. 25, 1941, pp. 9343-44. Also *Price Control Bill: hearings, committee on banking and currency, 77th Cong., 1st sess.;* Part 2, *H. R. 5479,* pp. 1152-53.

brilliant piece of economic analysis deserves a place in the *Review*. Mr. Smith is speaking:

"Up to June 30, 1940, the Treasury had acquired, nearly all from foreigners, roundly $13,000,000,000 of gold at $35 an ounce. By August 6, 1941 it was carrying on its books approximately $16,000,000,000 worth of gold at $35 an ounce, which represented the gold stock that was added to the amount held at the time of gold debasement, January 31, 1934.

"What did the Treasury use to pay for this gold? In section 8 of the Gold Reserve act is prescribed what shall be used to pay for it. It reads in part as follows:

" 'With the approval of the President, the Secretary of the Treasury may purchase gold in any amounts, at home or abroad, with any direct obligations, coin, or currency of the United States authorized by law, or with any funds in the Treasury not otherwise appropriated.'

"This is plain. It means the Treasury shall use money from its ordinary receipts, taxes, customs, and so forth, or direct Government obligations to pay for the gold it acquires.

"But does it pay for the gold it acquires with any of these payment media? The following colloquy took place between myself and Secretary of the Treasury, Mr. Morgenthau, at the hearings on the price control bill (p. 1152). It will be noted that Under Secretary of the Treasury, Mr. Bell, answered most of my questions, but specifically at the request of Mr. Morgenthau. Also it will be seen at the end of the colloquy, as shown here, that Mr. Morgenthau fully subscribed to all Mr. Bell said. Therefore, the answers to my questions are those of Mr. Morgenthau, as well as of Mr. Bell.

" 'Mr. F. C. Smith. What do you use to pay for this gold?'

" 'Secretary Morgenthau. Could Mr. Bell go through the operation of going to the bank and everything else?'

" 'Under Secretary Bell. If a country imports gold into the United States it is presented to the assay office, we will say in New York, and the New York assay office gives the importer or the bank or whoever it might be, a check on the Treasury, what we call a gold-fund check, and that check is cashed just like any other Government check. It is deposited by the recipient in his bank and creates a deposit.

" 'Then, when that check goes around the circuit and comes into the Federal Reserve bank it is charged to our account. It depletes the Government's balance with the Federal Reserve banks, and then in turn we issue gold certificates against that gold, and receive a credit for the gold certificates with the Federal Reserve Banks, thereby replenishing our account.'

" 'Mr. F. C. Smith. And you pay for the gold with gold certificates?'

" 'Under Secretary Bell. The gold pays for itself; it is money; it is just an exchange of one form of money for another.'

" 'Mr. F. C. Smith. What does the law say on that? Section 8 of the Federal [Gold] Reserve act of 1934 reads: "With the approval of the President, the Secretary of the Treasury may purchase gold in any amount at home or abroad, with any direct obligations, coin, or currency of the United States, authorized by law." '

" 'That is what the law prescribes you shall use to pay for this gold. What do you use?'

" 'Under Secretary Bell. We use a Government check which is payable in any coin or currency. Anybody can present that check to the Treasurer of the United States or a Federal Reserve bank and he can get currency or silver coin.'

" 'Mr. F. C. Smith. That is quite enigmatic. I am just wondering, is the cost of this gold reflected anywhere on the books of the Treasury? Does it enter into the debt?'

" 'Under Secretary Bell. The gold does not enter into the debt. It enters into the monetary system, and is shown on the daily statement every day.'

" 'Mr. F. C. Smith. Well, it does resolve itself into this, that you pay for it with a gold certificate.'

" 'Under Secretary Bell. We get a credit for the gold certificate that we issue to the Federal Reserve bank, which is backed by the gold.'

" 'Mr. F. C. Smith. But in the end, that is all that the United States Treasury gives out for this gold, is that true or not? Has it anything else to show that it paid for this gold except the gold certificate?'

" 'Under Secretary Bell. That is all that we have to show, but the importer of gold has a bank credit to show, or bank deposit to show for it.'

" 'Mr. F. C. Smith. But you have set up a deposit in the banks?'

" 'Under Secretary Bell. That is right; it increases the deposits. Gold earmarked in favor of a foreign government does not, of course, enter our monetary system.'

" 'Mr. F. C. Smith. But you printed the gold certificate, so you paid for the gold with fiat, did you not?'

" 'Under Secretary Bell. No; a gold certificate backed by gold is not fiat currency, if I understand the word "fiat." '

" 'Mr. F. C. Smith. But you bought the gold, purchased the gold, and now you set up a deposit in the banking system of this $15,000,000,000?'

" 'Under Secretary Bell. In fact, that is what was done, you exchanged the gold for a deposit in the bank.'

" 'Mr. F. C. Smith. Who exchanged the gold? The foreigner brought the gold in, and the Treasury issued a gold certificate and sent it to the Federal Reserve bank, which in turn set up a credit in some member bank in favor of the foreigner who sold the gold to the Treasury. Is not that the fact? It was given to the foreign merchant, or the foreign seller of the gold; that is the way the transaction operates?'

" 'Under Secretary Bell. Let us say the Chase National Bank brought the gold from abroad. Now, they own the gold, and they sell it to the Treasury and we give them either currency or a check and that is the payment for it. If some foreign bank imports it, then they get a credit on the books of the Chase Bank which is their payment.'

" 'Mr. F. C. Smith. When you issue currency that is a temporary proposition until you get the transaction adjusted, until you make your so-called gold-certificate deposit, and then your check transaction is canceled out. It is through the gold certificate that the credit in the bank is set up.'

" 'Under Secretary Bell. That replenishes our account and in fact the gold has paid for itself.'

" 'Mr. F. C. Smith. Would you say, Mr. Secretary, that the United States Government is carrying the cost of this gold?'

" 'Secretary Morgenthau. If you mean, are we carrying it on our books at cost, yes; but there is no cost to carry it.'

" 'Mr. F. C. Smith. Somebody paid for it; who paid for it?'

" 'Secretary Morgenthau. Mr. Bell tried awfully hard to explain it.' "

TEMPORARY NATIONAL ECONOMIC COMMITTEE: REVIEWS OF MONOGRAPHS

No. 4: *Concentration and Composition of Individual Incomes, 1918-1937.* By ADOLPH J. GOLDENTHAL. Pp. 112. 15c.

This monograph is a statistical study of the incomes in the upper brackets of the federal income tax returns in relation to the total number of income recipients and the total national income. It centers attention upon the concentration of income in the hands of the few and upon the changes in such concentration which took place in the two decades 1918-37. The measure of concentration is the proportion of the total national income which flows into the hands of the upper two per cent of the income recipients.

As measured in this study, concentration paradoxically increases with the increase in dispersion. The more the distribution of income fans out, the greater the likelihood of there being abnormally high incomes which, though small in number, comprise a considerable proportion of the total national income. It is largely because of this phenomenon that the monograph carries the conclusion that concentration of income increases with prosperity and high speculative activity and falls with depression.

The monograph contains many tables showing the shares in the total national income going to varying proportions of recipients in the upper income brackets. It also contains analyses of the composition of incomes in the higher brackets according to derivation.

MAURICE LEVEN

Washington, D.C.

No. 8: *Toward More Housing.* By PETER A. STONE and R. HAROLD DENTON. 1940. Pp. xxi, 223. 30c.

This monograph is concerned primarily with the provision of better housing for low-income groups and restoration of employment and business activity, and enthusiasm for these ends leads the authors into some rather indefensible positions. The assumptions underlying the argument and the statistical procedure are the features most likely to be questioned. The implied assumption that the building boom of the 1920's (1925-30) affords a norm is open to question since that volume of activity reflected an accumulated shortage, from the war years, federal restriction and the 1920-21 depression.

Implying that only new houses are suitable for those in need of better shelter, the monograph states, "There is a need particularly for the rehousing of 4,000,000 families which . . . must depend upon the use of second-hand houses when they have become depreciated to the point where they fall into the category of slums." About 85 per cent of this estimate of new building requirements represents units "in need of major repairs" as reported by the Real Property Inventories and which, if repaired, would be put "in reasonably good condition."

The report states that there is an annual need for at least 350,000 to 400,000 more units than are now being built in the price class below $4,000 "in order to meet the need of families with incomes below $2,000 and who . . . require new homes. . . ."

All will agree on the commendable goal of more good houses at low cost. It may be noted, however, that $4,000 is more than the average value of urban dwellings in 35 of the states even in 1930 before the decline in values that followed. The report errs in stating that only 19 per cent of new houses cost under $4,000, while 76 per cent of all families have incomes under $2,000 (Table VIII). This error results from assuming that the price distribution of new single-family dwellings accepted for insurance by the Federal Housing Administration is typical. These F.H.A. dwellings average far above the total for the country, being $5,000 in 1938, as compared with $3,450 for building permits—raised one-third for understatement and site. A recent Bureau of Labor Statistics study of residential permit valuations during 1936-38, in over 700 cities, indicates that new dwellings costing under $4,000 including the site were about 30 per cent of total urban building. This omits all dwellings reported under $500. The 1940 census reveals a vast additional amount of building in rural non-farm areas where prices are traditionally lower, hence new building under $4,000 may exceed 30 per cent. And since the Financial Survey reported that only 28 per cent of owner-occupant families acquired their homes by new building, acquisitions by income groups under $2,000 compare favorably with the average.

The assumption of a fixed relationship between value and income of 2 to 1, with rent 24 per cent of income (p. 25, Table VIII), fails to recognize the lower ratios for higher incomes. Sample studies indicate that for incomes of $1,500-$2,000 rent was only 19.7 per cent. Use of larger percentages of income for this group would purchase houses valued above $4,000 and increase the total.

The monograph assumes no savings, and debt as 100 per cent of value, whereas most purchasers make some cash payment. It assumes payments of one per cent of full value per month, hence a term of about eleven years, whereas payments recur on the unpaid balance and the term may be twice that indicated, such as with F.H.A.

Moreover, the implication that families not having new houses at prices under $4,000 cannot find adequate and livable housing within their purchasing power is contradicted by the 1930 census data that 40 per cent of then existing owner-occupied dwellings and 67 per cent of rented units were valued at less than $4,000. Allowance for the decline of one-third in value following 1930, would indicate that 74 per cent of existing units were within command of families with incomes under $2,000 for 24 per cent of income, or less. Hence, if 30 per cent of the new 540,000 houses in 1940 were occupied by low-income families, the provision of suitable housing for the remaining 70 per cent would require that only 2½ per cent of existing homes valued under $4,000 become available to these groups each year.

The chapter on housing costs concludes that site labor probably ranges from 25 to 45 per cent of the total cost, averaging about 30 per cent on one-

family dwellings. But in Part II it is estimated that the cost of all labor including original processes is from 73 to 89 per cent. It is therefore surprising to read that, "On the whole, there is no indication that high wage rates tend to discourage residential building, or that low rates tend to stimulate it." The report finds no correlation between wage scales and the cost of building activity and unionization, but the evidence is not convincing.

Discussing interest rates, the monograph states, ". . . the decline in effective interest rates between 1931 and 1940 is largely the result of various types of Federal intervention." Many would include consideration of the changes in international financial relationships. And again, "It cannot be said, at least for the time being, that a stated return is necessary to attract funds equivalent to mortgages." The report would have more value if it had considered the long-run consequences to housing of deficit financing, dilution of capital and artificial rate reduction which have brought about this situation.

It declares that, "with the passing of the Act setting up the U. S. Housing Authority, the Federal Government assumed the responsibility of providing decent housing facilities for those groups for which private industry does not provide." This may be straining the interpretation of this single measure.

Taken as a whole, the report tends to accept the existing set of cost-making factors and their methods of procedure and to discuss the housing question on the basis of assumed permanence of the prevailing situation. The principal hope extended for more housing is through improved technology supported by research.

Numerous informing sidelights add value to the monograph. The Appendix of 50 pages represents a useful compendium of data pertinent to the construction industry. The testimony of many witnesses warrants profitable examination of the hearings before the committee.

There are noteworthy omissions. There is no discussion of housing of small towns and villages and on farms, or of the great disparity between the value of urban and rural dwellings, averaging 5 to 1. In view of the official character of the report, more discussion regarding the relation of housing to the general economy would be welcome, as well as more consideration of alternative federal policies.

DAVID L. WICKENS

Washington, D.C.

No. 40: *Regulation of Economic Activities in Foreign Countries.* By LOUIS DOMERATZKY, RUDOLF CALLMAN, AGNES ROMAN, JOHN H. COVER, and NELSON A. MILLER. 1941. Pp. 177. 20c.

This monograph of 175 pages consists of seven parts dealing respectively with Great Britain (thirty pages), Germany (fifty pages), France, Argentina, Brazil, Chile, and Mexico, and an eighth part (two pages) of "Conclusions Regarding Latin America." Two-thirds of the part on Great Britain are devoted to the reorganization of the coal and cotton industries in the interbellum decades, preceded by a sketch of the general economic position of

the country after the First World War and the evolution of British governmental intervention in private industrial relations. The coal and cotton industry discussions are good factual summaries, but the absorption of attention in these two sick-industry cases results in the neglect of many important questions of British policy which a better planned monograph should be expected at least to touch upon.

The next part, comprising two chapters on the German experience, presents, in contrast to the part on Great Britain, a rounded and formidably documented survey of combination and control in German business, labor, and financial affairs. Yet in these two chapters, as in the rest of the monograph, the thinning effects of attempting to cover too much ground are shown in a tendency of the study to lose its often excellent analytical quality and lapse into generalities and tedious descriptive recitations of no very great significance. The "Conclusions Regarding Latin America" seem gratuitous and ill-advised, being little more than a collection of assertions, some unsupported and some of very doubtful correctness. The tone of this section is sometimes inappropriate as, for example, in the remark quoted from a popular magazine that ". . . having been mined for three centuries and milked for one, the Republics, particularly the more advanced Republics of Brazil, Argentina, and Chile, determined to do a bit of the mining and milking themselves. . . ."

Economic Theory; General Works

Monnaie, Prix et Change. Expériences Récentes et Théorie. By ALBERT AFTALION. Nouvelle édition remaniée et très augmentée. (Paris: Sirey. 1940. Pp. 565.)

When this new and considerably enlarged edition of *Monnaie, Prix et Change* (originally published in 1927) first went to press, it was presumed that the work would soon be available to every student of French monetary theory. The events of the war, however, have decreed otherwise. The present review is based on one out of seven copies which by chance reached the author himself in a town of unoccupied France. The reviewer, having been a student of Professor Aftalion and for a few subsequent years his assistant, feels less able to give a critical appraisal of the book from the point of view of current trends in American theory than to present its basic content as viewed from the perspective of recent French thought.

When the first articles of the author on the subject of money appeared in 1924 and 1925, it was possible to consider him as one of those unorthodox theorists whose provocative but consistently negative criticisms would stimulate strong and persistent opposition.[1] This feeling persisted even after the publication of *Monnaie, Prix et Change.* Nevertheless, the work quickly attracted a large audience in France, even among prominent defenders of traditional thought.[2] Thus, in spite of the opposition which other works on monetary questions by the same author still evoked,[3] this earlier book was well on the road to becoming a classic in French literature.

In part due to the discussion subsequent to the publication of the first edition, but probably due even more to the general advance in economics since that time, the issues at stake in the recent edition relate less to the soundness of the critical survey than to the validity of the positive theory, which itself has been the subject of attack by other theoreticians, *e.g.*, Hawtrey, Heilperin, and Marget. One of the most important features of this enlarged edition, therefore, has been to give more emphasis to the reconstructive parts of the analysis.

The author continues, however, to lay great stress on his polemics against

[1] The American reader will recall, for instance, J. W. Angell's very acute summary of his first article in *The Theory of International Prices* (p. 295), in which the question was raised as to how this "irreconcilable opponent of the quantity theory of money" would give "a complete alternative theory of his own."

[2] *Cf.* the article of Professor H. Truchy in the *Revue Politique et Parlementaire,* at the time of the publication of the book and, more recently, the frequent quotations made by Professor Baudin in *La Monnaie et la Formation des Prix* (Paris: Sirey, 1936), pp. 482 *ff.*, 493 *ff.*, 496-97, 516, *et passim.*

[3] *Cf.* criticism by Charles Rist in the *Revue d'Economie Politique,* 1937, pp. 381 *ff.*; and 1938, pp. 224 *ff.*, and rejoinders by Aftalion and Pirou in the same periodical, 1938, pp. 288 *ff.*, and pp. 438 *ff.*; and by this reviewer in the *Revue Economique Internationale,* Nov., 1937, and Oct., 1938.

the quantity theory of money in its various forms, but still in the simplest and least sophisticated presentations. The reason is, in part, that old errors, although repudiated, tend to reappear. But primarily, his method is for the purpose of cutting the roots of the more elaborate theories, so as to lead to the conclusion that any further examination of refinements would only result in wasted effort. If the all too famous man of straw did not exist, the author would have invented him; for he wants us to see men of straw behind apparently living bodies.

It may be conceded that some of Aftalion's criticisms have lost their provocative character. Much is today admitted of what seemed bold and new when current theory blindly implied, despite analyses such as Mitchell's in the United States and Nogaro's in France, that changes in circulation were, especially under conditions of paper money, the initial source of all monetary disturbances, or at least that "the price-level is the effect and cannot be the cause of changes in other factors" (an assertion in Fisher's *Purchasing Power of Money*, page 182, which many theoreticians thought necessarily connected with the equation of exchange, even though the more rigid interpretation that attributes all major changes in M′, V, V′ to the underlying influence of M were repudiated). In consequence, it is possible that some readers of the new edition will not venture beyond the first steps of the critical analysis, believing that the problems there discussed have been surmounted. (They may reappear before long.) But, after all, that would be an implicit tribute to a book which by its clear-cut analysis—with constant connection between searching statistical elaboration and rigorous abstract discussion—has played a major rôle in the controversy.

For a revision of the problems, the organization of the new edition merits definite approval. In the first edition, recent monetary experiments were presented in Part I; the theoretical discussion followed in Part II; and Part III dealt with the theory of foreign exchange. The great advantage of this approach, from a practical point of view, was that it provided a striking summary of French and European monetary fluctuations during the post-war inflationary periods with regard to the relative intensities, actual sequences and discrepancies in the movements of currency, prices and foreign exchanges during the different periods. This remained a necessary complement to studies such as those by Dulles and Rogers of the French franc and by Young or even Laughlin of European currencies. In the new edition, other statistical data appear relating to the depreciation period between 1931 and 1939, but all these data are now generally distributed throughout the various sections of the work. This organization of materials gives a much clearer picture of the author's methodological approach which proceeds from hypothesis to empirical verification at each step of analysis, although reflections of each chapter are only elements within the general theoretical study.

For those readers who may be impatient to get in a condensed form some clues to the author's analysis, it may be suggested that they go directly to Part III (Recent Experiments and the Theory of Foreign Exchange). It is not greatly modified, although it does contain a new chapter on the history of French foreign exchange from 1914 to 1939 and a new distribution of the

topics, with supplementary comments on the theory of manipulated exchange. A progressive criticism starting from oversimplified theories with regard to the "quantitative" point of view (balance of payments theories) and the "qualitative" explanation (purchasing power parity theory) leads to the "psychological theory of foreign exchange" where the necessary connections between qualitative and quantitative factors are shown in "three stages of explanation." Of course, it is not impossible to oversimplify the "psychological theory" itself, claiming, *e.g.*, that "it consists in opposing one aspect to another."[4] The question actually at stake is whether the "individual appreciations" can be relegated to a *first stage* of the approach (Heilperin) or necessarily come in at an intermediate one and cannot be dispensed with (Aftalion).

If we turn back now to the constructive scheme proposed by the author for his general theory of money, we may suggest that it is both less *simple* and less *exclusive* than many commentators thought. Most of the new developments are to be found in a new chapter II (Part II—Recent Monetary Experiments and the Positive Theory of Money), where he emphasizes his preference for the income approach in most cases. We already knew how he found its applicability in the cases where causation is going from foreign exchange to prices, and then to velocities; increases in the demand schedules coming from the nominal income of importers, shareholders of foreign securities, etc. More is said about currency issues for budgetary purposes, increases in gold production, credit inflation, and various kinds of influences from abroad.

The author also takes greater care to distinguish this approach from Wieser's, many readers having been confused by the tribute he paid to this theoretician who first pointed out the theory of the marginal utility of money income. But it was clear that Wieser did not have the same starting point and did not emphasize the influence of foreign exchange.[5] Furthermore, the author explicitly rejects all of Wieser's limitations concerning income outlays. Following this passage, he indicates the qualitative elements which have led him to surmount the *théorie du revenu* and to propose what he previously called the "psychological theory" and which he prefers, at present, to consider as the "positive theory" of money. (This title is given to Part II, yet the alternative terminology is also used.) This theory, after being verified in the light of recent experiments in England, Switzerland, and France (1931-39), is finally integrated—as in the first edition—in the general theory of value, with three stages of explanations showing how qualitative and quantitative elements work together, as for the theory of foreign exchange (which follows it in the book).

If we can realize that Aftalion's theory is less simple than generally believed when one tries to utilize his "income approach" as a substitute for the equation of exchange, we must add that it is less exclusive and even less ambitious too. For instance, he protests against Professor Marget's assumption that he generally considers the notion of velocity of circulation as an element of superfetation "which appears to be introduced in order to save the

[4] Heilperin, *International Monetary Economics*, p. 114.

[5] Ellis, *German Monetary Theory* (Harvard econ. stud., 1934), pp. 81 *ff*. and pp. 176 *ff*.

quantity theory of money": the expression he used in a particular case "does not carry a general import but does refer to the special hypothesis examined. . . ."[6]

We must recognize, however, that such an instance is of great importance. The author, challenging the traditional assertion as regards the "passivity of prices" in the equation of exchange, very often emphasizes the fact that rising prices are induced from rises in foreign exchange. Generally they themselves influence the V V′ factors through different increases of income and we can notice a process of progressive extension in the movement of prices beginning from import and export goods. The point at stake refers to a rapid movement in a period of extreme depreciation "without any processes of that kind." There is what the author terms "an insufficiency of the income theory," and a psychological explanation is required. However, the correct one would not be found in the increased velocity of circulation which follows from the fear of hyper-inflation, for the V factors cannot increase indefinitely as prices do (p. 245): "Is it not, in this case, this diffidence itself, this depreciation of the currency in the eyes of individuals, which would constitute the direct favor of the rise in prices?"

If we admit Aftalion's explanation, the demarcation line would not be between the quantity theory of money and the income theory, as suggested in Hawtrey's criticism of a "false antithesis" formulated by the author.[7] Both these theories are to be discarded as far as they would tend to be exclusive. A general and "positive theory" ought to explain all these reactions, even "psychological."

The author definitely discards the quantity of money approach, even for the "international theory of gold" (aggregate influence of gold production on world prices[8]); but here the income approach is only this "better explanation" that Professors W. Oualid and L. Baudin have in mind in their attempts at conciliatory schemes (Professor B. Nogaro remaining in France the most resolute anti-quantitativist).[9]

Very firm, however, in the rejection of the quantity theories, he never suggested giving up the "quantity equation" (to take Professor Marget's terminology) which, as he emphasizes, "has the great merit of compelling precise ideas" (p. 18). His particularly simple algebraic formulation: R (revenue, monetary income) = PQ, is not proposed as a substitute for the equation of exchange, but as a complementary device "exact only in certain cases" (first edition, pp. 157 and 175; second edition, pp. 179 and 225) and particularly useful to show discrepancies between PQ and R (which would equalize within an isolated country), or even between PT and PQ.[10]

[6] The author gives these precisions in a new footnote (p. 246, n. 1): ". . . introduced *at this point* [là], I have said . . ." *Cf.* Marget, *The Theory of Prices,* vol. i, p. 353.

[7] *Jour. of the Royal Stat. Soc.,* 1934.

[8] *Cf.* A. Aftalion, *L'Or et sa Distribution Mondiale,* Paris, 1932.

[9] For a bibliography of the French controversies, *cf.* L. Baudin, *op. cit.,* pp. 597-613.

[10] *Cf.* the distinction between *identical equations* and *equations expressing equilibrium conditions,* as emphasized in J. Marschak, "Identity and Stability," *Econometrica,* Jan., 1942.

We would have a better understanding of the author's attachment to the income approach if we could realize the rôle it played not only in this book, but also in his explanation concerning the re-equilibrating *stimulus* to the balance of international accounts[11] and even in his theory of cyclical fluctuations.[12] It is always an intermediate and necessary stage in his research, not at all a *first* approach or an ultimate answer. The author is never satisfied with simple formulae and tends to make (as did the Austrian school) a deeper psychological approach or even attempts general explanations that we may call "pluralist"[13] but are, at last, as the author points out, a scheme of the different influences acting on the supply and demand schedules.

One might be disappointed by these conclusions as they involve a reversion from quantitative statistical thinking to qualitative economics. The author, however, has shown himself to be, on all occasions, rather pessimistic.[14] But Professor Aftalion, while "anti-quantitativist" in the former sense, has given a sufficient impulse to "quantitative" economic research to give hope for an integration of more and more elements of statistical precision within the general framework he finally proposes.

Forty-five years ago, Walras welcomed the creation of an independent school of economics in the French law faculties which would put an end, in that country, to "a monopolistic exploitation under the sign of liberty."[15] Aftalion's scientific work gives evidence of the results obtained since that time. Just prior to the war some essays in his honor were ready to be edited by a second generation of economists which would have given a greater indication of the direction and ultimate implication of Aftalion's approach to economic analysis.

Jean S. Weiller

University of Poitiers, France, and
Institute for Advanced Studies, Princeton

Challenge to Karl Marx. By John Kenneth Turner. (New York: Reynal and Hitchcock. 1941. Pp. viii, 455. $3.50.)

The author's approach is distinctly one-sided: he is interested primarily in what is wrong with Marx. Such negative criticism undoubtedly has its uses but it also has serious dangers. It leads to a disproportionate emphasis

[11] *L'Equilibre dans les Relations Economiques Internationales* was only published in 1937, but the author had that idea in mind for a long time, as was suggested in newspaper articles quoted by the present reviewer (Jean Weiller, *L'Influence du Change sur le Commerce Extérieur,* Paris, 1929, pp. 182, 242, 253).

[12] We may go back not only to his very well known *Les Crises Périodiques de Surproduction* (Paris, 1913), but also to his thesis on Sismondi (1899).

[13] His different stages of analysis recall the different "depth-levels" of modern sociologists. *Cf.* Gurvitch, *Sociology of Law.*

[14] *Cf.* the conclusions of his recent book, *l'Equilibre dans les Relations Economiques Internationales,* rejecting both the self-confidence of orthodox theoreticians and the audacity of their opponents.

[15] L. Walras, *Etudes d'Economie Sociale* (Paris, 1896), pp. 456-57.

on inconsistencies, predictions that failed to materialize, tools of analysis we now regard as clumsy and obsolete. These are the inevitable accompaniments of the development of thought. Every creative thinker makes many false starts and arrives at conclusions by paths which later seem unnecessarily difficult. The task of sifting and evaluating is of course highly important. But its object should be constructive. Mr. Turner is too much concerned with exposing the defects in Marx and not enough concerned with discovering the things that are of positive value to present-day students of society.

Mr. Turner is in addition laboring under certain handicaps. He frequently points out that Marx's economics rests squarely on the foundation provided by Adam Smith and Ricardo. And yet he himself lacks the thorough-going familiarity with classical economics which is necessary to a full understanding of what Marx was driving at. The kind of error he falls into as a result is obvious in his discussion of the tendency to an equalization of profits:

> Before Marx, Ricardo had stressed the "emigration and immigration" of capitals as tending to produce an average rate of profit. It should not be necessary to say that there is no such mobility of capital as Marx pictures here. The farmer or merchant who is dissatisfied with the returns from his investment does not often find it possible to give up the old trade to manufacture automobiles or open a bank. If he is lucky enough to have surplus funds, he may buy stocks, but in that case he is more likely than not to lose his money, no matter how prosperous the enterprise may be (p. 140).

Mr. Turner further cites statistical studies to show that there is in fact no such equality of profits "as Marx imagines." The classical economists, of course, never said that profits in all lines would actually attain equality any more than they maintained that capital already sunk in one industry could readily be transferred to another. Mr. Turner would find if he re-read Adam Smith's chapter seven, "Of Natural and Market Price," that most of his difficulties were anticipated and satisfactorily disposed of by the great master. The same misunderstanding of the classical concept of Law comes out again in the discussion of the "Law of the Falling Rate of Profit," the "Law of Wages," etc.

A similar handicap appears in the author's lack of familiarity with the Keynesian theory of money, income, and employment. This lack is particularly serious in a student of Marx. Some of Marx's most important insights, ideas he was struggling to express with the inadequate analytical apparatus then available, become thoroughly clear for the first time in terms of the modern analysis. The latter, on the other hand, has much to learn from Marx.

Consider, for instance, the problem of accumulation. Mr. Turner's discussion starts out in promising fashion: " 'The life-process of capital consists only of its movement constantly expanding, constantly multiplying itself.' . . . the capitalist is a greedy fellow. In assuming the role of capitalist, he assumes the character of capital. 'His soul is the soul of capital. But capital has one single life impulse, the tendency to create value and surplus value. . . . Fanatically bent on making value expand itself he [the capitalist] forces the human race to produce for production's sake' " (pp. 104-05). But then Mr. Turner gets off on a sidetrack. He misses the vital point that the successful functioning of the capitalist economy is possible only under conditions which

permit the continued accumulation of capital. The modern investment-saving-income analysis brings out in detail why this is so. It shows exactly how an inadequacy of investment outlets produces depression and unemployment. Marx sensed the connection but was unable with the tools at his command to work it out in detailed, systematic fashion. His concept of accumulation, on the other hand, has important implications which the notion of saving lacks. Saving seems like too mild a force to produce such tremendous results. It is all too easy to assume that saving will automatically adapt itself to the need for it. Accumulation, on the other hand, is a relentless, driving force. It continues regardless of the need or opportunities for investment expenditure. Even depression and general impoverishment provide only a temporary stay. With every recovery of income, accumulation renews its pressure.

The analysis of accumulation—or saving and investment—throws significant light on other problems: wages, class conflict, international relations, the difficulties and possibilities of democratic action. These problems are greatly in need of serious and constructive analysis. Mr. Turner, unfortunately, has little to contribute on any of them, partly because his approach is chiefly negative and critical, but even more because he lacks the economic background necessary to understand what the real problems are.

ALAN R. SWEEZY

Williams College

Agricultural Price Analysis. By GEOFFREY S. SHEPHERD. (Ames: Iowa State Coll. Press. 1941. Pp. viii, 402. $3.75.)

For twenty years intensive research in agricultural prices has been going on, somewhat unnoticed by the majority of economists. Sometimes this work has been crude; sometimes, unfortunately, tied up too exclusively with attempts at price forecasting. Now after many years of critical review, the statistical procedures have been modified and, at the same time, reliance on statistical analysis has become less marked. In turn, more attention is being given to the integration of the statistical study with the analysis of the marketing institutions and with the new developments in value theory.

Professor Shepherd has brought together and integrated the work done by the statisticians, by the analytical students of marketing, and by the theorists. All in turn is interpreted in light of changing institutions, with particular emphasis on government policy. This material is presented for "the reader who has a grasp of economics equivalent to that which he would get from one or two good courses in economic theory, . . . who knows something about agricultural marketing," and "knows something about statistical methods."[1] Though prepared as a textbook for advanced undergraduates, it is of distinct value to the professional economist and to those responsible for the government policy, both with respect to agricultural and to urban economic activity.

The feature of the book which stands out most is that three approaches

[1] From the *Preface.*

to commodity prices are interrelated and integrated: (1) The character of, and changes in, markets for farm products are presented not only in an early chapter on "The Evolution of Markets and Market Price Making," but also appear later in such sections as that showing the effect of government policy and of market decentralization on future trading, and of government policy on the competitive character of agricultural markets. Then these institutional changes are brought to bear forcibly on both statistical analysis and theoretical study of prices. The exposition and statistical illustration of the "price surface" idea certainly makes more accurate and understandable the geographical concept of a market and price relationship therein.

(2) Statistical procedures come to life for the student when he sees them used for the analysis of specific situations. Though the book uses these cases (mostly hog prices) for illustrations, the selection of price situations serves to show the scope of statistical analysis. The integration of this analysis with institutional change shows, for instance, that correlation analysis is limited by changes in the character of the market, and that the development of a larger spread between farm and retail prices may arise from somewhat permanent institutional changes. Of still greater significance is the integration of the statistical and theoretical analysis. Such concepts as "demand elasticity" and "change of demand," or of supply, are vitalized by being worked out quantitatively.

(3) This integration becomes more marked when the food stamp plan and milk control plans, cases of price discrimination, are studied. Here the nature and significance of value theory become clear. Similarly, the incidence of the processing tax on hogs (on the farmer until output is adjusted), the process of adjustment in the hog and cattle cycles, and the variability of farm and retail prices, all rest heavily on theoretical analysis supplemented by quantitative study. At the same time, institutional change and theoretical analysis are interrelated as in contrast of farm and industrial production and price-determining forces, and in the exposition of government policy.

Another outstanding feature of the book is that price and production control are explained and evaluated in terms of this integrated institutional, statistical, and theoretical analysis of farm product prices. Without judging the conclusions with respect to public policy, it can be said that here is a forceful answer to those who contend that theory provides no basis for public policy. For both the institutional and the statistical study of prices become meaningless, if not impossible, without being preceded by, and integrated with the theoretical analysis.

A few minor weak spots are present; no one is basic. In the theoretical analysis, the reader is sometimes left with a feeling of incompleteness. The discussion of price discrimination is a case in point (chap. 20). In contrast, "demand elasticity" is treated fully and precisely. Again, the treatment of deflation theory and statistical procedures could be interpreted as giving support to the idea that the general price level is itself a cause of agricultural price movements. Agricultural folk have been so prone to accept monetary cures for their ills that any statement which could be looked upon as giving the "general price level" a significant rôle is unwise. A vigorous presentation of recent

developments in monetary theory would have helped here. In fact, the whole discussion of both agriculture and industry during depressions would have been more clear-cut and more accurate if the income-consumption-investment analysis had been expanded sufficiently to clarify the readers' ideas on booms and depressions.

Finally, two parts of the statistical procedures deserve criticism. The reader is not warned sufficiently concerning inadequacies of data used in price analysis, particularly as compared to small differences in elasticities, etc., derived from such data. Though market price (possibly not farm price) data are probably more accurate than most industrial price data, quantity data, which are often not marketed volume but production estimates, have a considerable margin of error. Then a significant limitation of multiple correlation analysis, the assumption that the influence of independent variable B is the same irrespective of the value of independent variable A, is not brought out.

These criticisms are minor, however. Pioneering work necessarily has such slight weak spots which disappear in successive editions. In fact, one hesitates to mention them in light of the obvious merits of the book. Certainly students who go through this book will gain a firm grasp of price analysis, and the professional economists who peruse the presentation with care will find a realistic exposition of price-making and will gain a clearer view of price control problems and policies, particularly in agriculture.

R. B. HEFLEBOWER

State College of Washington

Theory of the Just Price. By RUDOLF KAULLA. Translated from the German by ROBERT D. HOGG. (London: George Allen and Unwin. 1940. New York: Norton. 1941. Pp. 219. $2.25).[1]

The author of this book is quite aware that there can be no ideal, *a priori* just price. According to his analysis, ". . . prices of all commodites which are not strictly necessary to the satisfaction of vital needs can be maintained at whatever level suits the policy of the economic power-group concerned . . ." (p. 160). With respect to the necessities of life, however, an upper limit of prices and a corresponding lower limit to incomes are required. Should the prices of necessities tend to rise beyond the possibility of acquiring a subsistence-minimum, men will seek the aid of the state.

Elsewhere the author realistically discusses the rôle of government in resolving conflicts of economic interests (*e.g.*, pp. 182, 215). In the last chapter he considers governmental activity in connection with minimum wages, tariffs, and efforts to prevent the growth of monopoly. His own position is that "the State cannot help taking sides; it must do so, however, not in the interest of this or that particular group, but in order to serve the cause of the *common* welfare" (p. 217).

[1] The German edition of this book was reviewed by John V. Spielmans in *Am. Econ. Rev.*, vol. xxviii, Mar., 1938, pp. 120 *f.*

Kaulla stresses the importance of the legal structure in the determination of value. He maintains that state intervention is a necessity for a highly developed economic system. Contrary to the basic assumptions of prevailing economic theory, he asserts that "there are three terms, not two, in the problem of value: the object valued, the individual who values it, and the active presence of the *State*" (p. 95). Although the classical school stressed the object and the marginal utility school the subject, neither group considered state interference as anything more than an irregular disturbance of natural processes.

This is reflected, according to the author, in the attitude toward taxation, which has also been treated as a form of state interference in the "natural" course of economic life. Nevertheless, the persistency with which taxes continued to be levied required attention to problems of shifting and incidence. Such attention implies an interest in determining whether the taxes are "just." On the other hand, because of the underlying assumption of natural economic processes, scarcely any attention has been directed to the larger problem of the passing on of costs in general. From the point of view of just price analysis, this problem is obviously of the greatest significance, for the "justice" of prices depends ultimately upon the way in which costs are shifted.

The book's German origin is reflected in the author's constant use of the term "State." A more euphemistic expression would be more appealing to American readers. Nevertheless, the relationship of the author's thesis to American affairs cannot be altogether denied. As a matter of fact, a comprehensive study of American developments would be of considerable interest. Such a study might very likely suggest that in a rough and tumble way we appear to have been moving in the direction of "just" prices without often realizing it. Certainly the relationship between our agricultural policies, for example, and a just price analysis is fairly clear. A thorough study of all price-fixing might even suggest the need for a reorientation in the methods and objectives of political economy.

Meanwhile, those seeking clues which may be helpful in arriving at a more adequate theoretical summation of economic developments will doubtless find at least some features of this little book suggestive. It has been translated into good English and is easily read.

ALFRED BORNEMANN

Rutgers University

Essential Economic Principles. By ARCHIBALD MACDONALD MCISAAC and JAMES GERALD SMITH. (Boston: Little Brown. 1941. Pp. x, 504. $1.50.)

Essential Economic Principles is a revised version of *Introduction to Economic Analysis* and it is offered as an alternative to the latter. In general approach, the newer treatment follows the lines of the original volume. Certain chapters have been rewritten and some of the material has been rearranged but, with exceptions to be noted below, it is the same book in an improved form. One wonders about the location of the boundary line that

determines whether a new writing shall be called a revised version or shall rather be given a new title. However, to the teacher who must explain the advantages of product differentiation, this example offered by the publishing industry will be gladly received.

The book will of course be welcomed by those who believe that the chief objective of a beginning course is to give the student a clear grasp of the theory of value and distribution. Within this framework the treatment is impeccable.

The arrangement is conventional and logical. An examination of the simple concepts such as demand, the elasticity of demand, pure competition, leads up to a discussion of the short-run and long-run equilibrium of the firms and of the industry in conditions of pure competition and monopoly. The theory of distribution is also treated along conventional lines. There is an analysis of the relationship of a factor's marginal production and the demand for that factor and also of the significance of the elasticity of supply of the factor to the firm.

In the original volume, the connection between the demand for any factor and the cost functions of the firm was shown and it was shown that producer's demand could be computed in part from a knowledge of these cost functions. The present marginal productivity formulation, while it adds nothing to the substance of the earlier analysis, is probably to be preferred from a pedagogical point of view. This is perhaps the most substantial improvement in the rewriting.

The treatment of the interest problem is also somewhat better. Of course, it is by no means complete for there is no discussion of monetary institutions in the book; for that matter, there is scarcely more than an acknowledgment of the rôle of labor organization in the discussion of wages. However, it is unjust to criticize a book of this sort for what it omits. It is merely one of a series and it is designed for use in conjunction with other volumes in the series.

In comparing it closely with the earlier formulation, one is impressed with the ability of the authors to simplify certain parts of the original treatment that proved to be unnecessarily difficult. For what the authors try to do within the fields of value and distribution, there must be full praise. However, when with utterly inadequate weapons they venture out into the great world of aggregate demand for goods and factors, and of the business cycle, it is then that serious criticism is in order.

One does not have to rely on Keynesian doctrine to discover authority for pointing out the crucial difference between the effects of a change in any one variable; for example, in wage rates, on the firm or on a small industry on the one hand and, on the other, the effects of a similar change upon the whole economy. Professor Pigou also emphasizes this distinction. Value theory, as ordinarily conceived, is designed to explain the allocation of factors between industries and it can be used to explain the nature of the aggregate supply function. But it should not be used—or perhaps it should be used differently—to analyze what Keynes and Pigou call the aggregate demand function.

While we can derive the demand for labor in any one firm on the assump-

tion that conditions including wage-rates) in the rest of the economy are given, we cannot secure an aggregate demand function for labor over the whole economy by simply adding together these individual schedules. A complicated adjustment is required. Anyone who has struggled with the problem of the effect of a change in wage rates on employment will agree about the need for that adjustment although there will probably be no general agreement as to its nature.

A full treatment of this problem would perhaps not be possible in a book on this elementary level and, at this stage, there is perhaps too little agreement on fundamentals among students of such questions. But, in that case, rather than using weapons which were never forged for the treatment of business cycles and of the problems of aggregate demand, an elementary textbook could make a notable contribution by pointing out the uses and the *abuses* of the theory of the single firm and of the industry; that is, of our accepted theory of value. Its use within the appropriate framework is clear, but the temptation to use it outside that framework is difficult to resist.

In spite of all the authors have to say about price inflexibility and changes in weather and tariffs, and so on, in their discussion of these problems of the economy as a whole, they do not confine what they have so clearly expounded to its proper place. But in that respect they follow the example of almost all texts.

Otherwise, as has been noted, the book provides a clearly presented and up-to-date statement of value and distribution theory.

Economic History

French Interests and Policies in the Far East. By Roger Levy, Guy Lacam and Andrew Roth. I. P. R. inquiry series. (New York: Am. Council, Inst. of Pacific Relations. 1941. Pp. xi, 209. $2.00.)

An introduction and six chapters by Roger Levy, entitled "A Century of French Far Eastern Affairs," is ostensibly the pièce de résistance here. To the end of chapter III, France's cultural and economic achievements in China and Japan are ably summarized, with the warranted emphasis on missions. France's mediocre trade position is formally explained chiefly in terms of the small number of active French business men in the Far East. The character of French investments, which are mentioned in some detail, suggests a tendency to take fixed rates of interest rather than risks, but the author does not mention this point. Indo-Chinese trade, including that with France, is sketched on pages 22-26 in connection with Franco-Chinese economic relationships. This discussion could have been greatly strengthened by more attention to the imperial tariffs and the price levels involved. Chapter IV, on French trade in Southeast Asia and in the Pacific, is short and desultory,

with almost no emphasis upon Indo-China. The two remaining chapters deal with France and the Sino-Japanese conflict to about the end of 1938.

It is these last that Lacam's three chapters on the economic relations of Indo-China "supplement." In fact, they do far more: this paper is practically an independent one by a man familiar with the country and the trade statistics. Disorders in southern China, difficulties of communication which even railways and one good road could not overcome under peacetime conditions, the resistance of Chinese authorities to foreign economic collaboration, low purchasing power in southern China, and the lack of contrast in excess commodities are the main reasons given for the minor amount of trade across the land frontier and the inability of land routes to compete with Canton and Hong Kong for what there was. A final chapter of three pages sketches the effect of the war (or "China incident") for a little over a year, to "Munich."

Part II (French Indo-China in Transition, 1938-1941) is in a sense a "supplement" by Mr. Roth to the earlier part of the book, but it is work of quite a different character. Dealing with a short period, from Munich to about March, 1941, it justifiably—and necessarily, I think—follows a narrative pattern; for the timing of these events is all-important to any clear notion of their unfolding. The account falls into three divisions: I, from Munich to the outbreak of the European war; II, France at war, to the collapse in June, 1940; III, Indo-China adrift, from June, 1940, to March, 1941.

The author has used great industry and entire frankness in drawing upon what sources were available for such recent events in a region about which it has always been hard to get information. Especially considering the difficulties and the nearness of the events, this is an amazingly factual and calm recitation of one of the least credible dramas in modern history. It is an account of what the Japanese wanted in and with Indo-China and how they got it, together with the parts played by the French factions, the Chinese, the Siamese, the British and ourselves. Nothing short of the present situation, a year beyond this study, could have shown how revealing it genuinely is. Considering the ease of reading this book from pages 53 to 70 and from pages 85 to 197, I can think of few enterprises more to be recommended for getting a clear-cut general introduction to what is now going on in Southeast Asia. The account is itself so compact that an attempt to "review" it in a few paragraphs would be absurd. Incidentally, it is easier to criticize the French authorities, in Indo-China and in Vichy, than to point out exactly what they should have done.

Economic Systems; National Economies

The Structure of the Nazi Economy. By MAXINE Y. SWEEZY. Harvard stud. in monopoly and competition no. 4. (Cambridge: Harvard Univ. Press. 1941. Pp. 255. $3.00.)

Mrs. Sweezy's book, the fourth of a series of monographs on selected as-

pects of the general problem of monopoly and competition, is a well-documented scientific analysis of the structure of the nazi economy. Its only weakness, which cannot be helped, is the fact that Mrs. Sweezy's investigations, results, and conclusions are based on German official figures and statements. Mrs. Sweezy, however, has taken great pains in scrutinizing the official figures in order to determine their objective value and has used German statistical data with the utmost care. Her close observation of the working of the nazi system—made possible by a traveling fellowship—has enabled her to present a trustworthy picture.

The monograph begins with a short description of the status of Germany's economy before Hitler and of Germany's economy under Hitler up to the outbreak of war. As is commonly known today, the nazi economy even before the war began was a war economy and therefore few changes were necessary when war actually broke out. Mrs. Sweezy then shows the extent to which the state in Germany directs and controls economic activities. On the one hand, the Nazis hastened to return to private capital a number of monopolies held or controlled by the state, including banks, demonstrating thus to a capitalistic world their anti-socialistic tendency. On the other hand, they have built up—apart from Russia—probably the greatest state concern in the world—the Hermann Goering Works, a true industrial empire.

The best chapters of Mrs. Sweezy's book are those on corporations, income, consumption, and social welfare. Mrs. Sweezy has previously dealt with German corporative profits and the distribution of wealth and income under the Nazis.[1] Her analysis of the changes in the profit ratios for corporations is illuminating. It should be read carefully by all who are trying to understand the structure of the nazi economy.

Mrs. Sweezy tries to answer the all-important question as to who is gaining and who is losing in the nazi economy. Her conclusion that it is capital which has been favored by the Nazis will be doubted by many observers, but Mrs. Sweezy gives many facts to support her statement. A considerable rise in the profit ratio, based on the change from a depression period to a boom period, is contrasted with the stabilization of wages at the depression level. In spite of increases in employment and in working hours, the percentage of earned income in the national income fell from 69 per cent in 1929 to 63 per cent in 1938, while the percentage of total income from various kinds of property rose from 22 per cent of the national income in 1929 to 28 per cent in 1938. The average inequality was greater in 1935 than in 1931. However, it should be noted that, at least for the duration of war, all capital is at the disposal of the government and though no confiscation has taken place, capital had "voluntarily" to give up the right to dispose of its money at will. There is, however, as Mrs. Sweezy points out, one group in Germany which appears unequivocally to draw special favors from the Hitler government, and that is the National Socialist Party and its affiliated organizations. Many of its functionaries have entered the field of industry and all who are in the

[1] See *Quart. Jour. of Econ.*, May, 1940, pp. 394-98; *Rev. of Econ. Stat.*, Nov., 1939.

unfortunate position of having to compete with them are at a distinct disadvantage.

Mrs. Sweezy destroys the legend of a superhuman genius who directed Germany's financial system. She shows that Germany's price and financial policies never followed a preconceived plan. Each emergency was met as it appeared. All who hold that the collapse of German economy is just around the corner on account of its faulty financial policies will be disappointed. The German system seems to her to be soundly based on a tight control over capital and investment markets and over wage rates and prices.

Not quite up to the standard of the book is the chapter on regimentation and conscription of labor. Mrs. Sweezy evidently takes the German labor front as a labor union. She believes the Nazis have "reorganized" the labor unions because "The National Socialist Government recognized that destruction of the labor unions might strengthen radicalism among the workers" (p. 161). But the Nazis *did* destroy labor unions.[2] Nor do the Nazis deny it.[3] Not for a second would the Nazis allow the German labor front to be taken as a labor union, and any attempt to classify it as such is condemned to failure. The labor front consists of employers *and* workers. The employers do not have "representation" in the labor front, but they are a part of it. In addition, the labor front has no authority to deal with matters concerning wages, hours of work, or other working conditions, which are the main objectives of a labor union.

Strikes have never been prohibited by law. Labor disputes, if not settled by mediation, still go to the Labor Courts,[4] while the jurisdiction of the Social Honor Courts is confined to different types of violations, as enumerated by Mrs. Sweezy on page 166.[5] Overtime for the ninth and tenth hours of labor was restored by an order of September 3, 1940, as a consequence of continued resistance on the part of the workers.

Mrs. Sweezy is right in saying that the provisions of the Social Honor Courts seem to be directed mainly against workers and less against employers. But, contrary to expectations, the majority of the cases brought before them have been directed against employers.[6] The reason probably is that there are other, more effective means available to the authorities for dealing with violations on the part of the workers. Experience so far has fully confirmed Mrs. Sweezy's other contention that, as far as the employer goes, the law is likely to be applied against owners of small shops. Out of 189 cases against employers which arose in 1936, nearly three-fourths involved handi-

[3] See *Bulletin of the World Economic Archives of Hamburg*, No. 13, May 1, 1935, p. 6.

[4] Not to the Social Honor Courts; see Sweezy, p. 164.

[5] The enumeration leaves out the most important offense: A member of the confidential council can be punished "if he interferes deliberately in the conduct of the establishment or maliciously disturbs the community spirit in the works community."

[6] In 1936 the Social Honor Courts had to deal with 251 cases, 189 of which were directed against employers. See *Pol. Sci. Quart.*, 1938, p. 366.

crafts, agricultural, and small industrial enterprises. It should be noted that the figure of 251 cases in 1936 for the whole of Germany is very small indeed and has since further declined.

Mrs. Sweezy's book is a most valuable contribution and will help to clarify many confused notions which are current regarding the structure of the nazi economy.

JOSEPH MIRE

Washington, D.C.

A French View of the Netherlands Indies. By G. H. BOUSQUET. Translated by PHILIP E. LILIENTHAL. (New York: Oxford Univ. Press, for American Council, Institute of Pacific Relations. 1940. Pp. viii, 133. $1.50.)

As a foreword explains, much of the "Moslem policy" part of the original French book on *Dutch Moslem and Colonial Policy* is omitted from the translation, and a chapter on the international position of the Netherlands Indies added. The English title does not fully suggest the peculiarities and limitations of the study.

Professor Bousquet went to study Moslem policy. This would seem to exempt him from references to Indo-China. However, he admits that the Indonesian culture is largely intact beneath the Moslem superstructure in the Netherlands Indies, and frankly regrets his inability to make the suggested comparisons. This still seems to me lame, for he asserts the superiority of French policy, in material respects and particularly in spiritual ones, without proper allowances for the fact that North Africa is a really Mohammedanized country in the Temperate Zone and at the doorstep of Europe. The author admits that the "modern reform movements" in the Netherlands Indies, though Moslem in name, have been basically nationalist in fact. This does not apply to North Africa, save to some extent in Tunisia.

Political reforms since 1900 have not given the Indies a parliamentary system, which Professor Bousquet thinks they need. The French example, if any, somehow escapes me. Nevertheless, some criticisms of the extreme rigidity of Dutch native administration, regardless of high-grade personnel and the most detailed of cultural investigations, are much to the point. This general policy of minutely planned paternalism is modified in a curious way which Vandenbosch and others are criticized for neglecting. "Prentah aloes" or "gentle compulsion" introduces local flexibility of action into the general system as seen on paper by the use of oral rather than written instructions. Thus what is flatly illegal can be done locally without serious danger of a rumpus, since nobody is formally responsible and everybody has an interest in keeping the surface smooth.

There are chapters on the "process of civilization" (the "progress" of Europeanization, largely) and on "Dutch colonial character" (compared with French). The added chapter on the "International Position" deals with trade, with the rights of culture groups, etc., quite briefly. There is not much on "conditions" in the sense of the economist as such. Nevertheless, this is an

illuminating "background" book under an English title which is not so illuminating regarding the subject matter.

Statistics; Economic Mathematics; Accounting

Statistical Cost-Functions of a Hosiery Mill. By Joel Dean. (Chicago: Univ. of Chicago Press. 1941. Pp. ix, 116. $1.00.)

Since studies of empirical cost functions are all too few relative to the interest in the subject, this recent contribution should be welcomed by all. It seems evident to this reviewer that if progress is made in economics, it will come from such studies as these which attempt to analyze actual data in the light of a formalized methodology. It is better to measure imperfectly than not to measure at all, for only through actual measurement can we appreciate the unreality of our theory and the complexities of concrete situations. Professor Dean has been a pioneer in the field of cost determination, and this recent study reflects the wealth of experience acquired in previous research.

His treatment of the data shows an appreciation of difficulties that may arise when dynamic facts are considered as elements in a static schema. Careful selection of his time period and of the particular plant studied greatly increased the validity of his analysis. For example, constancy of the size of physical plant, a minimum amount of technical progress, stability of management, uniformity and completeness of cost records, and a number of observations large enough to permit generalization were all sought and are quite well achieved in the present study. The existence of a wide range of output was also attained, but unfortunately the variation occurred mostly between two periods, one of a high level of output and the other of a much lower level. According to the data in Chart 13 (p. 49) output was between 3,000 and 4,800 dozen pairs for the first 34 months and between 400 and 3,000 pairs for the last 14 months.[1] This is a very serious flaw in the data since it is very difficult to separate those changes due to time from those changes due to output. In the last period we have no output equivalent to that of the first period and so cannot analyze the variance that might have occurred in the cost of identical outputs at different periods. Furthermore, there is a bunching of the observations around certain output levels seriously impairing the significance of the correlation technique which is used in analyzing the data.

The rectification and adjustment of the various costs is very well done in light of the many difficulties present. For example, the cost of silk was omitted "partly because the dominant importance of this variable cost would obscure minor departures from linearity in operating costs and partly because silk cost could be allocated to individual items with sufficient accuracy to raise no problem in the determination of marginal cost. Since silk costs are assumed

[1] Data in this chart present costs instead of quantity, but conversion of costs into quantity can be simply computed since this chart assumes linear total cost.

to be proportional to output, their elimination may prevent rather than induce an exaggerated appearance of linearity. The justifiable suspicion that silk costs might increase more than in proportion to output at extreme levels of operation as a result of wastage and spoilage is not borne out by the analysis of replacement cost" (p. 38). In other words, Professor Dean has not approached the problem by a hammer-and-tong method in following literally the dictates of the theory, but has rather used an intelligent appreciation of how to achieve his purpose by other than direct methods. The breakdown of costs used is quite extended, certainly coming up to the standards required by the problem. Furthermore, intelligent omission of such things as stationery, traveling expense, freight and express, building repairs, oil, etc., seemed quite justifiable on the ground that they would have little to do with the shape of the cost function or else that they were relatively unimportant and would contribute little to the analysis. The use of monthly data greatly facilitates the employment of lags in relating cost to the proper output.

After such treatment of the original material, Dean then presented his rectified and adjusted measurements in the form of scatter diagrams. One could well wish that more writers would follow his excellent example since this form of analysis enables the reader to gain a better understanding of the data than could be achieved by any possible number of statistical devices. It is unfortunate, however, that nowhere in the whole study were the original or adjusted data given in other than scatter diagram form. This made further computation on the basis of Dean's data impossible and many readers will be quite disappointed since no checks, other than those occurring in the analysis, can be brought to bear on the reliability and significance of the regressions.

These scatter diagrams substantiate a point which was mentioned above, namely, that the majority of the cases are concentrated within a small range of output. Over forty per cent of the observations occur within an output range which is only ten per cent of the total output range; within an output interval constituting over fifty per cent of the total output range, only seventeen per cent of the observations may be found (p. 22).

Output	0	4	8	12	16	20	24	28	32	36	40	44	48
No. of observations	1	3	4	2	2	0	1	2	4	18	10	1	

The scatter diagram reveals one more important factor to be considered. In the ten per cent of the range of output within which forty per cent of the observations lie, the variation of costs is quite wide. For example, an output of 37,000 pairs of silk hosiery cost at one period $60,000 and at another period $90,000. This is most disturbing in light of the highly rectified data which have been deflated for all price changes. Indeed it casts serious doubts on the significance of the values obtained for observations in other parts of the output range. It is quite proper to ask the question as to whether, if the observations had been more numerous, we might have had an equivalently wide scatter over the other parts of the range of output. If this were so, the

correlation coefficients would be much lower than those which were actually found by Professor Dean, and absolute linearity of the total cost functions would be almost impossible to establish.

It is unfortunate that Professor Dean does not develop the analysis of these variations. Perhaps some sort of procedure such as accountants use in explaining the variance of actual cost from the standard cost set-ups could be employed here. Influences other than merely output variation have had a decided bearing on cost. Dean's nearest approach to solving this problem is the exploration of a number of independent variables in order to ascertain their effect on cost. With the exception of the magnitude and direction of change of output from the previous output period, all the independent variables were found to be of little importance.[2] Further analysis indicated, according to Professor Dean, that linearity was present between the average first differences of cost and magnitude and direction of change in output. In other words, "short-run changes of cost tend to be proportional to changes in output regardless of magnitude or direction of the change" (p. 43). It must be noted here that this does not mean that the total cost output regression is linear. The above linearity can exist with curvilinear total cost output regressions if the level of output and the magnitude and direction of output change are unrelated.

Actual analysis of the rectified data of cost and output is developed according to whether it is productive labor cost, non-productive labor cost, or overhead. The total of these becomes combined cost. Linear regressions were fitted to all sets of the data and the justification for such procedure was based on: (1) analysis of marginal and average cost behavior, and (2) analysis of curvilinear regressions.

Unfortunately no scatter diagram was given for the relation between average first difference and output. We are told that a horizontal line fitted the data best, but no supporting evidence is given. The correlation is extremely low, .18 ± .15, and it is hinted that the scatter is quite wide (p. 43). It would seem probable, in light of the correlation and wide scatter, that quite a few non-horizontal lines might be fitted. Certainly there would not be much danger in lowering the correlation coefficient by very much. Average cost analysis yields a regression which decreases with increasing output, approaching a horizontal position at the highest level of output, if the wide scatter is neglected. Unfortunately, however, we should not neglect this since the exact shape of the average cost function is important. In any case, even if a regression of the type suggested were the correct function, all this would tell us would be that marginal costs did not rise appreciably above average costs at high levels of output. In the case of both marginal and average cost analysis, then, it is impossible to choose between linear and non-linear total cost output regressions since both could occur with the existing data.

The statistical tests of linearity, furthermore, are no more satisfactory. Dean has shown quite ably that the regression coefficients of the parabolic

[2] Some of these are: Style variation, difference in specifications, seconds, backwinds, transfers, replacements, style changes, specification changes, difference in piece rates, technical progress, shifts, labor turnover.

and cubic regressions are small relative to their standard errors so that zero coefficients for the squared and cubed terms are quite probable (and thus linearity). This, however, is no solution. Unlike other mathematical situations, it does not follow here that the less complicated function is better if fully as significant as one of a higher order. In an economic sense, a linear relation is no "simpler" than a curvilinear relation. Furthermore, it will be seen from Dean's analysis that curvilinear relations are statistically as signficant and probable as linear relations. He is quite right in pointing out that, while the cubic regression fitted to the data may be statistically probable, yet, due to the fact that its signs are opposite to those needed to describe the marginal cost curve of economic theory, we may quite well reject this curve. Since, however, the standard errors of the squared and cubed terms are large relative to the coefficients, it would be quite possible to have, within the standard error limits, an orthodox U shaped marginal cost curve which varied considerably over the range of output. In reality we find that no test rejects a linear regression, but neither does any reject a curvilinear regression. It would have been of great interest had Professor Dean divided the data into two groups—for example, outputs 0-20 and 24-48— and then fitted linear regressions to each of these groups. If this had been done, I believe that the slopes of these regressions would have been found to be quite different from each other. This should not occur if the sample were sufficiently reliable and marginal costs actually constant over the given range of output.

The statistical tests of linearity as conceived by Professor Dean seem to admit strong probability of large variation in marginal cost. In the parabolic equation the standard error of the squared term is large enough to allow the possibility of either increasing or decreasing marginal cost.[3] If the true coefficients of the squared term were at the lower limit of the standard error, then at 4,000 dozen pairs marginal cost would be about 90 cents above the marginal cost at 45,000 dozen pairs. If the true coefficient were at its upper limit of the standard error, marginal cost at 4,000 dozen pairs would be 64 cents below the marginal cost at 45,000 dozen pairs. This would represent a large percentage change since marginal cost of a linear regression figured by Dean came to about $2.00. The cubic equation, being of a higher order than the parabolic equation, could naturally exhibit fully as much variation as the parabolic curve, since by considering the cubed term as very small or zero we would have a parabolic curve. Since actual data are lacking, estimation of marginal cost variation in this case is difficult.

It is interesting to note that in the appendix, where weekly data are analyzed, marginal cost of the parabolic curve falls from about $3.75 when production is at 4,400 dozen to about $1.50 when production is at 8,000 dozen. The range here is smaller than in the case of monthly data, and yet the variation is considerable. The reason Professor Dean rejects a parabolic

[3] It has already been noted that the distributions of observations are in no sense "normal" and so, as Professor Dean points out (p. 48), "the conditions necessary for the validity of such tests are not met by the cost and output observations. This may mean that the limits of error are much wider than those presented here."

regression in the case of weekly data is based on the argument that the monthly data yield linear regressions. In the opinion of this reviewer, there is no greater statistical evidence for constant marginal cost than there is for increasing, decreasing or parabolic marginal costs. I would be inclined to agree with Professor Dean, however, that constant or nearly constant marginal costs are probably correct in the case of this mill. My impression of this is derived from the excellent description of the mill contained in this study and not from the empirical cost data which are presented. The possibility of this conclusion being wrong cannot be statistically checked due to the limitation of the empirical cost and output data.

It is important theoretically that such uncertainty arises as to what the actual shape of the marginal cost function may be. If an entrepreneur cannot know within a wide margin what his incremental costs may be, we find that much of our theory will break down. In one sense we are interested not in what the cost function is, but what it is considered to be by the producer. Therefore, if it is impossible to discover empirically what the function may be, it may have little or no relation to what the producer believes since he too will be in a state of ignorance. Dean has presented us with a case in which the dynamic elements have been eliminated as carefully as possible, but reality is even more complex and the producer is forced to consider these elements. It is easily conceivable that the concept of sharp-edged equilibrium may have to be revised and limits set up within which it is realized that cost elements will not determine the quantity of output. Perhaps cost analysis as revealed by empirical cost studies can never solve the problem of what actual cost output relations would be. Further exploration of the cost function may quite well be in order by concentrating on the physical counterpart of those cost items which are crucial in the analysis of marginal cost. In any event, the efforts of Professor Dean are a valuable contribution in this field, revealing many of the difficulties that must be met.[4]

Harvard University

Public Finance; Fiscal Policy; Taxation

The Taxation of War Wealth. By J. R. HICKS, U. K. HICKS, and L. ROSTAS. (New York: Oxford. 1941. Pp. x, 304. $3.50.)

A more timely book than this would be difficult to imagine. Presenting an interesting and, considering the pressure under which it must have been written, a remarkably thorough analysis of the excess profits tax and the capital levy, this volume is required reading for anyone seriously interested in the problems of taxation during a period of intense war effort.

[4] In connection with this review, attention is called to an article by Mr. C. Reinold Noyes, published in the September, 1941, issue of *Am. Econ. Rev.*, pp. 473-92, "Certain Problems in the Empirical Study of Costs."

The contents fall into two well-defined parts. There is a theoretical analysis concerned with the general problem of war finance, but placing especial emphasis upon the kinds of taxes which are presumed to fall upon incomes associated with the effects of the war effort itself, and the so-called "capital levy." In addition, there is a series of chapters which presents in summary fashion the experiences of nations that have already attempted the application of this sort of taxation. The latter will not prove quite as interesting to most readers, who will be well advised to focus their attention upon Parts I, II, and V which contain the generalizations relating to the proper form and rôle of the taxes on war wealth, and for which Mr. J. R. Hicks assumes primary responsibility.

The central thesis is laid down in the Preface and runs as follows:

"The greater part of the cost of war needs to be met out of taxes which fall in the ordinary way upon ordinary incomes." Based as it is upon a comparatively thorough study of the special taxes associated with war, this conclusion is apt to be quite unpleasant to a great many people, especially those who are inclined to place major emphasis at the present time on the development of the excess profits tax. And yet it is very difficult to disagree with Mr. Hicks's conclusion. The main objective of war taxation is the control of consumer income. If this is to be accomplished a tax system must be constructed which is broad in its scope, quick and flexible in its impact. The war taxes discussed by Mr. Hicks are not very satisfactory when judged by these criteria.

The excess profits tax is, in the absence of the extreme price inflation which it is supposed to assist in preventing, relatively narrow in its impact; fails for the most part to tap the chief source of consumer income, wages. In this respect it is even less satisfactory than a tax on corporate net income would be, and the latter itself cannot qualify as the chief weapon in a war finance scheme because it has a relatively narrow scope.

If constructed according to traditional plans, the capital levy would fall beneath the same charge. It too would miss a large proportion of the total income of the civilian economy; it too would have to be supplemented with other taxes, and the latter rather than the capital levy itself would be the primary instrument for the control of consumer income.

From the point of view of flexibility and rapidity of collection neither capital levy nor excess profits tax makes a good showing. By its very nature the levy cannot serve as a part of a continuing program and the delays involved in its administration are notorious. The excess profits tax might be made to give some flexibility to a revenue system, but the extreme difficulty of defining excess profits and translating the definition into detailed administrative rules tells heavily against the possibility of even reasonably prompt collection. This is a very serious defect from the point of view of the primary objective of war taxation.

Yet Mr. Hicks is aware, as all of us are, that extreme pressure will be applied to use these special war taxes as a means of extracting a large contribution from persons in the upper income brackets. Moreover, Mr. Hicks is aware that a failure to satisfy the demand for this sort of taxation will be

quite unfortunate in that it will place a selling point of major importance in the hands of people who are attempting to head off measures intended to control lower bracket incomes. Hence the conclusion can be reached that at least the excess profits tax is desirable even though it ought not to be treated as the keystone of a war tax program.

The question then arises as to the form which such a tax ought to take. There are two fundamental choices which must be made. Is the tax to be imposed on the excess profits of business or corporate business taken alone? Or is the tax to be a general levy on added income applying to persons as well? The second question is the choice between a tax levied on high incomes generally and one which is aimed specifically at additional income obtained during the war period, which is over and above that arising during the years prior to the impact of the war boom.

The somewhat guarded approval which Mr. Hicks bestows upon an added income tax on persons used as a supplement to an excess profits tax on business must be viewed somewhat critically if one has in mind the application of the conclusions reached to the tax program of the United States. A tax on added income of this sort requires a comparison between income received during the pre-war and that of the war period. The data for such a comparison are meagre in this country because of the limited scope of the pre-war personal income tax. This fact, taken together with the added difficulties of administration involved, raises a distinct presumption against a levy of this sort in our own case, especially when the measure is used as a substitute for additional rates applied under the ordinary personal income tax. While this conclusion seems inescapable, it is disappointing because the idea of a general tax on war income is very attractive in itself and becomes increasingly so when one observes the erratic manner in which the war affects the economic status of particular individuals.

Mr. Hicks also bestows his blessing upon the so-called "war profits" as contrasted with the "high profits" form of excess profits taxation. This boils down to the general use of the so-called "base period income" formula, a most interesting conclusion in view of the implicit approval bestowed upon the form of the excess profits tax now in use in this country, especially since that form has been the object of persistent criticism on the part of the federal treasury and recently has been attacked by a very distinguished American student of excess profits taxation.[1]

The objection to the position taken by Mr. Hicks is easy to see. The process of constructing a tax on base period income grants unusually favored treatment to firms enjoying large profits in the base period, including those firms whose profits are ordinarily large because of monopoly position. Yet the logic of a tax calculated on base period income is far more appropriate to the desire to levy upon the windfall profits of a war period than the sort of levy which is constructed on the basis of excess profits defined in terms of a percentage return on the investment in the enterprise in question. The latter

[1] C. Shoup, "The Taxation of Excess Profits," *Pol. Sci. Quart.*, vol. lv, pp. 535-55; vol. lvi, pp. 84-106; 226-49.

form is far more consistent with a policy designed to set up a permanent tax on high profits intended to serve primarily as an instrument for attacking the so-called "monopoly problem." There is considerable reason to believe that this is the underlying objective behind the current proposal to amend the excess profits tax so as to eliminate the option to use the base period income formula. To precipitate at this time a debate over the use of taxation as a device for trenching upon monopoly position seems distinctly unwise from a political and economic point of view. If, on the other hand, the object of the legislation is restricted to the taxation of war profits, Mr. Hicks's conclusion and the implicit support of the form of tax now in use in this country seems fully justified.

Mr. Hicks has a good deal to say concerning economic incentives during a war period. He is inclined to the opinion that at least during the early years of the war effort, care must be taken not to take away so large a percentage of marginal income as to dampen unduly the enterprise of the business community. This means of course an implicit condemnation of very heavy rates under the excess profits tax. Clearly the 100 per cent rate formerly in use under the British levy was ill advised and the substitution of a blocked account for the last 20 per cent of this rate was fully justified by Mr. Hicks's logic. It may well be, however, that he underestimates the need for a profit stimulus during the later years of the war effort. So long as any substantial body of policy decisions remains in the hands of private enterprise the wholehearted coöperation of the business community is vital for the war effort, and the complete or nearly complete elimination of the motive to which that section of the community ordinarily responds is dangerous from the point of view of the success of the war effort itself.

Mr. Hicks's chapters on the economics of the capital levy are well worth reading. They are in fact the first serious analysis of this proposal since the time of the Colwyn report. While the general result of his treatment is to reduce somewhat the fears which have become traditional concerning the possibility of financing the collection of a tax of this sort, the impression remains that a very real problem exists. The collection of a heavy tax would be a delicate operation at best and this counts seriously against its use during periods of great stress when nicely conceived devices requiring precise and deliberate administration are not apt to receive the attention which they deserve.

As we have already pointed out, this book is an important contribution. Invaluable as a source of information concerning the fiscal policy of today, it fills a major loophole in the general literature of public finance.

EUGENE E. OAKES

Yale University

The Economics of American Defense. By Seymour E. Harris. (New York: Norton. 1941. Pp. 350. $2.75.)

This volume is an essay in applying "the principles of economics to the problems of war and defense. It is both a tract on public policy and an exercise in economic principles" (p. 7). As an exercise in economic principles it examines the structure and functioning of a war economy; as a tract on policy, it analyzes the American defense program in the light both of its legacy from the depressed thirties and of its presumptive bequest to the post-war world of the future. While these two broad fields of interest are obviously interdependent, it is convenient to examine them separately.

In real terms the economic impact of war involves the attempt to maximize specific goods and services at the disposal of the state. The means whereby this is done include the centralized control of foreign trade so as to reduce exports and increase imports, the stimulation of output, the discouragement of consumption, the cessation of capital formation or replacement in non-essential industries, and the diversion to the state of the resources so freed (p. 55). In monetary terms, the problem involves providing the state with the dollars necessary to purchase the goods and services it needs by methods involving a minimum of dislocation, hardship and, above all, competition with the state for scarce resources. The existence of this financial problem has, in the past, tended to obscure the "real" problem just stated. Professor Harris quite rightly reiterates that fundamentally the financial problem is a secondary one, thus recalling the dictum of *The Economist* that the first charge upon financial policy is to see to it that nothing is ever decided upon financial grounds. Given the basic task—increase in output and diversion of resources—how can it best be accomplished?

To the extent that idle resources are available, they can be mobilized simply by bidding for them. For this reason, the extent of unemployment should be regarded as an important determinant of governmental policy (p. 50). But the existence of bottlenecks, the pressure for speed "beyond the system's ability to adjust real resources" (p. 139), and the immobility and specificity of many resources soon exert an upward pressure upon prices which brings the issue of price control to the fore. To the extent that inflation facilitates the expansion of necessary output and increases the income of the treasury, the author is not hostile to its appearance (pp. 149-50), although he recognizes the need for its control. The reviewer would agree that, for political reasons at least, some degree of inflation is all but inevitable in a war economy; that scarcely needs pointing out in the United States of early 1942. But he feels that there are two points to which Professor Harris could have given greater consideration and which might modify the conclusions reached in the volume under review.

The first has to do with idle resources. It has become semi-fashionable to accept increases in the quantity and velocity of money as long as these are matched by corresponding increases in output. Professor Harris correctly calls attention to the fact that, in such a process, prices begin to rise considerably before the point of theoretical full employment has been reached. This suggests that such a rise in prices may reflect inability to supply (the

bottleneck issue), and at once raises the question whether further price increases have any stimulatory effect upon output. Given time, the situation may adjust itself; but under the conditions of modern war, time itself tends to be scarce, and cannot easily be spared until self-corrective forces have come into operation. The author mentions in one or two places (*e.g.*, p. 73) the desirability of utilizing price increases as incentives. This presupposes a greater degree of mobility, and rapid mobility, than may, in fact, obtain, except in the very early stages of rearmament which by now have been passed. It also raises questions about the use which the recipients of increased prices make of their enhanced incomes, which obviously should not be spent in competition with the government for scarce resources. Given the state's need for resources, use of the price incentive as a mechanical rabbit would seem to be advantageous only as long as the rabbit is never caught!

This brings us to the second and more fundamental point, which has to do with the consistency of the classical price function itself with an economic war effort. High prices, traditionally, serve the twofold purpose of stimulating output and restricting demand. Once resources really become scarce, not only are the possibilities of expanding production reduced, but high prices may actually have a deleterious effect upon output. There is some ground for believing that, during the last war, certain marginal producers of copper and coal, brought into production by the prices then prevailing, actually drew resources (especially labor and transportation facilities), away from more efficient plants which could have used them to better effect.

The same ineffectiveness exists on the demand side. No government at war will ever let its demand for resources be restricted by the height of the prices it has to pay. And, apart from foreign trade, there is no limit to the *monetary* resources which a state can bring into the market. Civilian demand may be restricted by mounting wartime prices, but only to the extent that increases in wages, profits and other incomes fail to keep abreast of the increases in commodity prices themselves.

Carried to its logical extreme, the principles of war economics can be reduced to three basic procedures: people must be assigned tasks on the basis of national need, irrespective of differential financial incentives (this, of course, is done in so far as induction into the armed forces is concerned); individual incomes should be paid on the basis of need, irrespective of the occupation of the recipient; and the distribution of goods and services should take place under the complete administrative control of the state, irrespective of the means of payment in the hands of consumers. No nation has yet carried matters quite as far as this, which means that, as far as policy is concerned, the problem is even more a political than an economic one. The decision as to how "totalitarian" a modern democracy must become in order to wage war effectively will, and should, be based not only on the state of the budget, the severity of bottlenecks and the interrelationships among prices, but also on the state of public opinion, the urgency of the crisis and the anticipated ease of the projected post-war transition back to peace.

With respect to American policy, Professor Harris has many sensible things to say. The fact that the United States has become a belligerent since

the book was written requires certain modifications in detail but few in principle.

The defense program itself is examined against the setting of recent economic history and in the light of its rôle as "arsenal of democracy" which the United States was playing at the time the book was written. Parts of the section on the international position of this country may need revision if recent hints that the belligerent democracies are contemplating the pooling of their financial and material resources are ever carried through.

Some of the most interesting portions of the book have to do with the financing of the war and the control of inflation. In principle, the author discerns three stages in the transition to a full-blown war economy. (His suggested time table [pp. 175-76] needs revision in view of the recently announced war budget of fifty-six billions.) The first stage, characterized by the progressive utilization of hitherto unemployed resources, is accompanied by deficit financing, moderate tax increases and increased tax yields; the second is marked by continued deficit financing, increased reliance on taxation and the commencement of borrowing out of genuine current savings; while the third stage finds increased reliance upon consumption taxes and a proportionate decrease in the deficit in relation to total expenditures, even though, in absolute terms, the deficit may continue to increase. Professor Harris, wisely, is not an alarmist about the size of the debt, pointing out (pp. 314-17) that the extent to which it may become burdensome depends on other factors, such as the size of the national income, to which primary consideration should be given.

The most serious criticism of the American defense program to be found in the book is directed against its lack of integration. The responsibility for tax policy, monetary policy and price policy is concentrated in different governmental agencies, and each policy has been formulated more or less independently of the others. Yet the close interrelationship between prices, money and finances, income, consumption and, again, prices should mean that taxation, price control and borrowing are jointly moulded into a dynamic, flexible, over-all economic policy. The concluding chapter of the book is devoted to just this topic: a criticism of the defense program up to the early fall of 1941, with suggestions for its improvement.

The book is not an easy one to read. It is characterized by an attention to detail that sometimes obscures the underlying significance of the details themselves. But it is a mature treatment of the economics of *this* war; and, for readers in this country, at any rate, not its least valuable feature is its integration of the theory of war economics with a discussion of the applications of that theory to contemporary American problems.

George P. Adams, Jr.

Cornell University

Paying for Defense. By ALBERT GAILORD HART and EDWARD D. ALLEN, with others. (Philadelphia: Blakiston. 1941. Pp. viii, 275. $2.50.)

The authors present an analysis of the problems of fiscal policy confronting the country in the national emergency. Upon the basis of this analysis, a positive program is constructed and its probable economic consequences indicated. Although the book was of course written before the United States became fully involved in war, its timeliness is not thereby seriously affected. The authors' estimates of revenue required must now be revised upward substantially; but what they have to say with regard to the objectives and methods of fiscal policy is as applicable now as before.

The primary objective of fiscal policy is of course to raise the necessary amount of revenue for defense needs. But the problems that are really troublesome are those involved in the choice of methods of raising the amount required. These are the problems with which the authors are mainly concerned. They list six objectives as of determining importance in the choice of methods of defense financing: (1) to maximize output; (2) to prevent an inflationary increase in the general level of prices; (3) to attain a distribution of burdens according to ability to pay; (4) to give everyone a sense of sharing in defense; (5) to release resources needed for defense; and (6) to promote, as far as possible, a healthy financial structure. By far the most stress is placed by the authors upon the second and third objectives.

A careful analysis is presented of the extent to which reliance may safely be put upon expansionary and non-expansionary borrowing, leading to a consideration of the volume and the methods of taxation which will be necessary and desirable to raise the required amount of revenue. Throughout the analysis, the emphasis is upon the necessity of achieving an equitable distribution of burdens and of preventing inflation.

In the program of fiscal policy which emerges from the analysis, principal reliance is placed upon the income tax, on the ground that the great increase in revenue required could most equitably be raised from this source. Hence it is proposed that a revenue of ten or twelve billion dollars should be raised by this tax during the year 1941-42, the increase in revenue from this source to be effected by lowering exemptions about one-half and by appropriate increases in rates. To make the tax more effective in checking inflation, it is recommended that the tax be collected during the year in which the income is earned, mainly through collection at source, and that the rate be varied, possibly as often as monthly, whenever variations in a cost of living index indicate either an inflationary or a deflationary tendency.

The general sales tax as a means of raising all or any part of the necessary additional revenue is rejected on the ground that our tax system is already regressive, that such a tax would tend to raise prices to consumers, thus providing a basis for demands for wage increases which would further the inflationary tendencies already operative, and that it would be relatively inefficient as a curb upon the spending of those in the high- and middle-income brackets. Excess profit taxes can probably be relied upon to raise some of the increased revenue required, but are regarded as relatively ineffective means in proportion to the amount needed. Excise taxes on goods whose

production conflicts with defense needs should be used to absorb the excess profits which otherwise might accrue to the producers of such commodities whose supplies have been restricted. The government should raise funds by borrowing only in so far as this can be done without prices rising. Every rise in the cost of living should therefore be accompanied, or promptly followed, by an increase in the income tax rate and a decrease in borrowing.

There will, I believe, be general agreement with the authors' stress upon the desirability of attaining a distribution of the burden of war finance in accordance with ability to pay, and upon the importance of having all taxpayers conscious of their contribution. Hence there also should be general agreement with the authors' preference for the income tax as that source of increased revenue upon which primary reliance should be placed.

Nor should any question be raised as to the desirability of levying sufficient taxation to block inflation. Here the authors' stress upon promptness of collection is also appropriate, and I find myself in agreement with them as to the importance of introducing collection at source to as great an extent as may be administratively feasible. I seriously question however the desirability, either from the administrative or from the economic point of view, of adopting the authors' proposal for frequent changes in the income tax rate. I am afraid that they underestimate the seriousness of the uncertainty, from the point of view of the taxpayer, that would result, and that they overestimate the feasibility of the use of simple statistical criteria as a basis for quick administrative action with regard to rate changes.

The authors also, in my opinion, have underestimated the possibilities of non-expansionary borrowing as a source of revenue in time of war. The heavy income tax which they propose, even though it be highly progressive, involves a very serious burden for the lower income groups. The even heavier tax which would now become necessary might involve an impossibly heavy burden for these groups. Even a highly progressive income tax will place more of the burden of financing the emergency upon the lower income classes than will a program of non-expansionary borrowing. It is true, as the authors point out (p. 82), that in the period of debt repayment spending power is likely to be transferred from the lower income groups to the higher income groups; but the authors fail to note that during the war period in which the debt is increasing, the use of non-expansionary borrowing in effect shifts some of the burden of war finance from the lower income groups to the higher income groups. With the burden of the war finance program as large as now appears likely, considerable reliance upon non-expansionary borrowing will not only be desirable but also probably unavoidable. Although the authors do devote some attention to the possibilities of compulsory loans, I am afraid they have failed to appreciate their possibilities to the full.

A minor criticism has reference to the argument in favor of excise taxes on commodities the production of which involves the use of resources required for defense purposes. The authors favor such taxes as a means of drawing off excess profits that otherwise might arise as a result of the restriction upon output. In effect, this proposal represents the use of excise taxes as a partial substitute for excess profits taxes, and to that extent the argument appears

sound; but it also represents the use of excise taxes as a means of rationing scarce goods. For if the excise tax on a given commodity is sufficiently high to draw off the whole of the increase in price which otherwise would result from the restriction in supply, then the tax must be sufficiently high to raise the price to that level at which the quantity demanded would be no more than equal to the limited amount of the commodity produced. This is a very inequitable method of rationing. Much more desirable would be the institution of price control and consumer rationing in the case of such commodities.

Readers of the book will appreciate the clarity and brevity of the authors' exposition. They will also admire their courageous, and on the whole, cautious and helpful use of available statistical materials.

B. F. Haley

Stanford University

American State Debts By B. U. Ratchford. (Durham: Duke Univ. Press. 1941. Pp. xviii, 629. $5.00.)

An encyclopedic review of the past experience of our states in the exercise of their credit and an attempt to deduce therefrom helpful conclusions to guide them in their future borrowings are presented in *American State Debts*. Two-thirds of the book are devoted to a chronological account of the development of state borrowing from the colonial period to the present time; one-third deals with current problems and suggestions for their solution.

A sharp contrast is drawn between the debts incurred by the colonial governments and the states prior to 1800, which were comprised largely of paper money issues and debt certificates of irregular amounts, were largely "forced" in character and were incurred for the financing of wars and operating deficits, and the debts incurred after 1800, which took the form of regular negotiable bonds, were voluntary in nature and were used mainly to finance capital outlays.

The course of modern state borrowing, which really began in 1820, is divided into five periods. The first, running to 1840, was concerned with internal improvements, such as the construction of canals, turnpikes and railroads and with the organization of state banks, and is shown to have been a failure in the sense that it ended in widespread deficits, repudiations and financial losses to the states. The second period (1845-1860), similarly characterized by borrowing for internal improvements, is shown to have been a somewhat lesser failure, due to the greater care exercised by the officials in the selection of the projects to be financed by loans. The appraisal of the results of these borrowings follows the traditional financial pattern. No acknowledgment is made of the fact that these borrowings, even though they had resulted in losses to the treasury, might have conferred benefits on the community nonetheless.

The nature of the constitutional restrictions on state borrowing adopted toward the close of the two periods mentioned, under pressure from irate taxpayers, is described, but unfortunately the political and social implications

of these restrictions are not brought out as clearly as they might have been. No suggestion is advanced, for example, that the complete prohibition embodied in many of these restrictions on the contraction of any debt by either the legislature or even the electorate itself, for any purpose except the suppression of an insurrection, might have been unwise in that it closed the field of internal improvements to the state governments concerned completely for many years to come, leaving this field to be exploited solely by private corporations interested merely in earning profits. The abuses of state credit during this early period are evaluated too much in terms of present-day standards and not enough in terms of the general speculative setting which characterized all economic operations of this time.

The third period of development of state borrowing, associated with the financing of the Civil War, is deemed to have been partly unsuccessful, inasmuch as it was attended by inflation and, in the case of southern states at least, also repudiation. The fourth period, associated with the borrowings of the southern states, under gang rule, during the Reconstruction Era and similarly culminating in a series of defaults, is admitted by the author not to have been a "fair example of state borrowing."

Having reviewed these somewhat unsavory pages in the history of the American state debts, the author turns to the modern (fifth) period of their development, running from 1910 to 1940, and characterized by borrowings of a multi-purpose nature. The author is loath to admit the greater orderliness of state borrowing during this period and its basic difference from the unfortunate earlier experiences of the past. He takes the position that "it is still too early to formulate a final evaluation of this period, for most of the loans have yet to be repaid," thus indirectly suggesting the possibility of new state repudiations and defaults. He is willing to admit that the borrowings for highways and unemployment relief of this period have been socially worth while. But he believes that the loans for veterans' bonuses and the debts incurred by some western states for the establishment of systems of rural credit, after the collapse of farm prices in 1920-1921, have been unjustified, and he withholds judgment as to the worthwhileness of the loans contracted for other purposes. It is not clear to the reviewer wherein these other loans, which have comprised such projects as grade crossing elimination, bridges, state parks, additions to university buildings, hospitals, aid to public housing, harbor improvements, development of water supplies and reforestation, have been less desirable than borrowings for highways or unemployment relief.

State officials are taken to task for having neglected to use during the 1920's the callable type of bonds, which eventually would have saved their states considerable sums in interest payments since these bonds could have been refunded during the 1930's when interest rates dropped sharply. The fact is overlooked, however, that no one even among the experts advising the officials anticipated at the time the occurrence shortly of a sharp break in the interest rates or advocated the use of this type of bonds. The underwriters, who were an important part of the market, as the author admits, were adverse to its use. In the light of this, it is not clear how the officials

could have done otherwise than to adhere to the more traditional forms of borrowing. The experience of the 1930's should serve as a lesson for the future to all state and municipal officials and students of public finance regarding the advantages of introducing greater flexibility in the terms for which bonds are issued, but it certainly does not demonstrate the lack of foresight on the part of any particular group of individuals.

The section on current problems is opened with two case studies—those of Arkansas and Tennessee—which bring clearly to the fore the evil consequences of the failure by a state to plan carefully its borrowings and debt repayments. This is followed by a discussion of constitutional debt limitations, which, unfortunately, is too descriptive and not sufficiently critical in character. The author should have considered at this point the pros and cons of these limitations. Instead, he limited himself merely to a statistical comparison proving that constitutional restrictions restrict borrowing. Next comes a review of court interpretations of these limitations, and of the remedies left to bondholders to secure the enforcement of state loans; and a survey of some of the dangers involved in the unrestrained use by states of the "limited obligation" type of bonds, commonly known in the market as "revenue bonds." In a chapter devoted to the present geographic distribution of state debts, their concentration in the Northeast and Southwest is pointed out. This concentration is explained by the greater maturity of these regions, the poverty of the southern states, and the special prominence of "machine politics" in some of them.

The economic effects of state debts are treated in a chapter of only some seventeen pages. The discussion is rather academic, bears little relation to the rest of the book, and is confusing. The disadvantages of state borrowing are emphasized, while the advantages are slurred over. Borrowing is said to promote extravagance, inefficiency, graft, and irresponsibility among officials and overconfidence among citizens generally, and to create false booms. It tends, according to the author, to generate more borrowing and, by producing a heavy debt burden, to rob the state of its freedom of movement and ability to meet new emergencies. Eventually, by necessitating large repayments, it is said to exercise deflationary effects on business. The only real advantage seen in borrowing is that it makes possible the execution of activities on a large scale, but even with respect to this advantage, some limiting factors are suggested. No distinction is made between the economic effects of well-controlled borrowing and those of loose or excessive borrowing. Yet such a distinction would have been exceedingly serviceable in view of the recommendations made in the concluding portion of the book for the liberalization of the existing constitutional debt restrictions and a better planning by the states of their borrowing generally.

The plea for a liberalization of these debt restrictions is based mainly on the argument that they are being evaded through the issuance of revenue bonds. This plea would have been more convincing, and also more in accordance with the facts, had it been based upon a demonstration that state loans, when well planned, can confer immense advantages on a state; that such a planning of them is scarcely possible under the existing debt limitations, and

that there exists today in many of our states, as a result of a complete overhauling of their administrative machinery in recent years, the competence necessary for making effective such planning of the use of their credit.

The author recommends the conferring on the state legislature of a power to incur debt up to an amount equal to the annual current revenue of the state during the preceeding five years, with a power for the electorate to borrow, by a special referendum in each case, up to another such sum, and for the legislature, in the event of a proclaimed emergency, to borrow up to an additional 50 per cent of such amount. Thus, the aggregate debt limit applicable to normal times would amount to 200 per cent of such average current revenue, and for emergency times, to 250 per cent of it. In addition, debts of self-supporting enterprises would be made completely exempt from the debt limit. These are sensible proposals. Except for the fact that the limits are to be based on the average current revenue instead of on the average assessed valuations, they follow to a large extent the arrangments which have been in effect for many years in the case of municipal borrowing and which have operated there with reasonable satisfaction. The substitution of current revenue for assessed valuations, as a basis for the limitation of state debts, is logical inasmuch as state revenue (on which the ability to take care of the debts rests) is derived mostly from other sources than the property tax.

The final section of the book is replete with excellent recommendations. The states are urged to proceed slowly with the exercise of their credit. Many of the mistakes of the past are laid, quite rightly, to excessive haste in the authorization of the loans. Great emphasis is placed on the need for establishing capital outlay budgets and long-range financial planning, the financing from current revenue of at least a small portion of the cost of each outlay as a "down payment," the shortening of the terms of bonds to 25 years, the use of callable bonds, and the resort to state borrowing mainly during periods of depression.

These excellent recommendations, however, would have been more forceful had they been supported more fully with confirming opinions from the existing literature on the subject and references to the successful experimentation with some of the proposed devices by the more progressive states and municipalities in recent years. In general, the book suffers from an insufficient emphasis on the improvements introduced by the states in their borrowing practices in recent times and from a failure to indicate clearly that most of the abuses of their credit took place in the distant past. A reader who has been told that "it is not feasible to make any general statement as to whether the states have, on the whole, realized a net advantage from their borrowings" (p. 583) will find it difficult to follow the author's recommendations for a broad liberalization of the existing limitation of state debts. This statement, in the reviewer's judgment, has some semblance of correctness only if the unfortunate but really irrelevant experiences in state borrowing of one hundred years ago are indiscriminately lumped together with the more fortunate and relevant experiences in such borrowing of modern times.

But, despite these shortcomings, the book is to be commended as a piece of formidable research and first-rate scholarship. It is profusely documented

and will be of great value to persons interested in state bonds as an investment, officials concerned with the management of state debts, and students of public finance generally. It is written simply and clearly and should exercise a wholesome influence upon the future course of state borrowing. Its appearance at a time, when, because of a preoccupation with national defense, a lull in state borrowing is setting in, is especially appropriate. This temporary relaxation in state borrowing should afford an opportunity to the officials concerned to perfect the arrangements necessary for the exercise by their states of their credit more intelligently and effectively during the next period of efflorescence of internal improvements and state participation therein, which is likely to follow on the heels of the present defense period.

PAUL STUDENSKI

New York University

Money and Banking; Short-Term Credit

Money in Motion; the Social Function of Banking. By A. C. HOLDEN. (New York: Harper. 1940. Pp. vii, 242. $2.50.)

The author, for twenty-five years an architect engaged in large-scale house construction, was impressed by the imperfections of long-term finance in the industry. He is convinced that dislocation, unemployment and depressions are largely, if not completely, due to the lack of a reorientation in the capital goods enterprise. The heart of the problem lies in striking a balance between production and consumption, between the cost of capital goods and the continual revenues derived from them. Long-term finance must learn to amortize long-term debts out of the utilities thrown off by the capital produced: witness such instructive instances as toll-bridge finance, installment buying and house rentals, where gradual payments measure the succession of utilities and alike provide the means of liquidating the long-term credit which gave birth to the durable agents.

Long-term finance is to borrow a page from the ideal conception of short-term credit extension. The commercial banker is not, or should not be, a mere merchant of money, ready to lend so long as "collateral" is provided. He is rather supposed to judge the supply and demand for the goods of the producer seeking accommodation; and a grant of bank credit is to symbolize that the production of the goods is justified by the market conditions. A similar conception ought to govern long-term credit for capital goods. To allow savings alone to determine the course of investment is to give hostages to fortune, for a disparity exists between the ebb and flow of savings and the fluctuating requirements of funds for capital formation with solvency and stability as the paramount objectives. The dislocations are compounded by the profit motive and high rates of interest as the arbiters of investment.

These criteria of allocation do not guarantee the equation between cost and utilities and above all the liquidation of the long-term credit involved.

What is needed is a Capital Reserve banking system, not unlike the Federal Reserve system in structure, embracing all the saving and investment institutions in the projected districts. It will be the function of the new institution to extend long-term credit, beyond the pool of savings if need be, at varying but low rates of interest. The master purpose will be the mitigation of depressions and the flattening and lengthening of the business cycle generally, by employing idle productive forces and by redirecting resources to new employments. The guide will be, not primarily profit and interest, but careful study and planning and an effort to match potential demand with new projects.

The significance of the book goes beyond the central thesis, which possesses flaws obvious to the student of economics. The author is a fine example of what college presidents have in mind when they talk of a liberal education. The book combines a pleasant style and a wide-ranging view with a tolerant attitude to social critics and reflections on social psychology. The nature of banking, of hoarding and saving, of installment buying, and of amortization are expounded with uncommon pedagogical skill. It is a good book for the business man because it opens new vistas, points to new responsibilities, and paints the function of business on a broad canvas and with perspective.

The Security Affiliates of National Banks. By W. Nelson Peach. Johns Hopkins Univ. stud. in hist. and pol. sci., ser. lviii, no. 3. (Baltimore: Johns Hopkins Press. Pp. 187. $1.50.)

The 1941 addition to the Hopkins studies in historical and political science describes at some length financial developments of the twenties which led to a decline in importance of that aspect of banking which long has been regarded as strictly commercial. During that same decade investment banking was enjoying an era of unprecedented prosperity. As the effective demand for good commercial loans declined banks were forced to invést an increasingly large percentage of their funds in securities and to make loans in large volume secured by stocks and bonds in the process of distribution or being used currently as media for speculation by the banks' own customers. As these phases of their activities grew more important large metropolitan banks found it necessary to develop bond departments and to keep in close contact with all aspects of the securities business. The way was thus paved for banks to enter the investment banking business in spite of limited powers in this field. In an era so reckless and speculative it would seem strange indeed had the device of the security affiliate failed to make an appearance.

Using as his principal examples the security affiliates of the Chase and the National City banks, the author describes the abuses growing out of the affiliate system. Most of the resulting evils might have been eliminated by corrective and regulatory legislation; yet there would still remain the funda-

mental defect—mixing the commercial and investment phases of the banking business.

Since security affiliates have been abolished presumably permanently, the study is valuable principally to students of financial history. For a work so scholarly and so well documented it makes unusually interesting reading, for it throws considerable light on business and banking standards of an era now dead but never to be forgotten.

International Trade, Finance and Economic Policy

Inter-American Solidarity. By WALTER H. C. LAVES, editor. Lectures on the Harris Foundation. (Chicago: Univ. of Chicago Press. 1941. Pp. xiii, 228. $1.50.)

This volume of seven assorted essays is typical of the repetitious parade of writings in the last two years which has served very little to advance realistic understanding of the economic issues of inter-American policy. Professor Upgren's presentation, in the section on "Raw Materials and Inter-American Solidarity," is substantially a reiteration of the thesis and facts given by him in collaboration with Professor Bidwell in an article in January 1941. Twenty of the fifty pages in the section on "Inter-American Trade and Financial Problems" are consumed in expounding a naïve theory of international investment. To this the remaining discussion appends some considerations respecting the Latin American position, leading to a series of "Conclusions," the tenor of which may be judged from numbers one, three, and nine: "1. As a natural and inevitable result of economic laws, whose workings are beyond her control, the United States is bound to export capital. . . . 3. Owing to reasons dictated by her own internal economy, and also to conditions prevailing today in international trade, the United States must inevitably export capital to Latin America. . . . 9. The past experience of British investment in the United States does not seem to confirm the fears that Latin America may become an economic rival of the United States." The three sections entitled "What Have the Americas in Common?" "Cultural Relations Among the American Countries," and "Pan Americanism and the World Order," are largely rhetorical, and the first of these is marred by several careless generalizations. Major Eliot expounds in the fashion of a formula his well-known ideas on modern warfare in his section on "The Strategy of Hemisphere Defense." Professor Frank Scott's contribution, "Canada and Hemispheric Solidarity," on the other hand, is thoughtful, substantial, and attentive to neglected questions.

HORACE G. WHITE, JR.

Washington, D.C.

Business Finance; Insurance; Investments; Securities Markets

Investments. By George W. Dowrie and Douglas R. Fuller. New York: Wiley. 1941. Pp. viii, 631. $4.00.)

Many textbooks on investment have a serious defect. They either cover a wide range of material properly covered in other undergraduate courses or they give primarily a generalized financial survey of subjects. It is not enough for a course in investments merely to generalize on background material and financial analysis. The student should be taught how to administer an investment fund. This entails a knowledge of fundamental problems and forces in investment, the significance of investment policies and plans, and the evaluation and selection of specific securities. *Investments* by Dowrie and Fuller has accomplished this job for the student in a very satisfactory way.

Although the book covers a wide range of material on investment, the treatment of the subject, on the whole, is conservative, timely and effective. The book is well balanced, its organization is good and the presentation is clear. It is quite evident that the authors have a good background in economics and practical investment plus the ability to present their information in a compact, satisfactory text.

The authors state that the book is designed "to present principles applicable to all forms of investment and to introduce the reader to the major problems which each of the more important special aspects of the subject presents." This purpose is accomplished to a substantial degree. The book is not primarily a treatise on the technique of investment. More largely it emphasizes and analyzes the fundamental forces creating the hazards of investment, the principles and criteria determining investment values, and the need for an investment program.

The book begins with an introductory setting of three chapters wherein the nature of investment is presented, an historical perspective of the problem is given, and the supply of and demand for capital is analyzed. Part II, "The Mechanism of Investment," comprises four chapters dealing with bonds, equities, investment banking, and the security markets. There is nothing new in these chapters either as to subject matter, organization, or method of treatment. This is important material, however, for students beginning the study of investment. It is also very helpful to general readers unfamiliar with such subjects. In Part III, "Investment Policy," four chapters are devoted to the risks of investment, primarily those arising through external influences such as cyclical changes, changes in purchasing power, and changes in money rates. Five chapters are given over to investment policy, individual and institutional. One chapter is on governmental protection and regulation, in which also is discussed "the vital part taxation may play in the determination of an investment program." There is important material in this section which will help the student or investor to understand the need for an investment program. But before a sound investment plan can be formulated it is essential to have an understanding of the various forces which may affect investment

policies. The survey of institutional investors is short but it gives a good idea of their nature, fundamental investment problems and how they have been met.

The fourteen chapters of Part IV on "Investment Analysis" take up nearly half the book. One chapter is included on sources of information. Financial statements are explained in two chapters. The chapters on selection of investments—on which the major emphasis of this division is placed—include general considerations, corporation bonds, civil obligations, real estate and real estate obligations, and common stocks. Here investment analysis is employed for the purpose of providing the investor with a sound basis for determining investment values. There is presented the fundamental elements in the appraisal of each type of fixed income obligation. The methods of analysis are clarified by concrete illustrations in which actual companies are examined. Common stock selection is predicated upon the investment analysis approach. Specific factors are examined and individual companies are studied to illustrate the process of selection.

Part V is a single chapter of thirteen pages on investment advice and management. Here is a concise and fair discussion of professional investment management, and the problem of managing one's own funds.

Certain aspects of investment are omitted or receive inadequate treatment. Inflation is treated incidentally in the chapter on the purchasing power risk. War as a factor in investment is only mentioned. A chapter is given to the stock exchange, but security speculation is omitted. There is no mention of the mathematics of investment. There are very few footnotes and no bibliography, questions, or problems.

While the book has its weak spots, it has so many good points that we may consider it a real contribution as a text for those working in investment.

N. GILBERT RIDDLE

Ohio State University

The Regulation of Stock Exchange Members. By RAYMOND VERNON. (New York: Columbia Univ. Press. 1941. Pp. xvi, 152. $2.00.)

The scope of this concise treatment of the regulations of stock exchange members is limited to the various aspects of broker-dealer-specialist transactions. Despite this limitation the area remains large, and it is surprising to find the material covered so adequately in a small monograph. The author has done an excellent job of balancing the discussion of the many topics covered and of stating the essential points clearly.

This is not another treatise on the economics of stock exchanges; the subject enters only incidentally into the discussion. Instead, the book might be described as an exploration of the logic of exchange member regulation. The principal emphasis is on the aims of regulation, and on the confusion generated by certain rules which work at cross purposes.

The first and fifth chapters are very brief. The first states the "aims" of regulation but not in any detail. The author has merely listed certain claims for and against exchange trading, and indicated some of the difficulties of

regulating transactions involving member interest and the public interest. The fifth and last chapter contains general discussion of such phenomena as "fair" markets and "orderly" markets, and is based on S.E.C. and Senate reports and hearings.

The main part of the work, chapters 2-4, is devoted to the following broad topics: (1) regulation of lending and borrowing activities of brokers; (2) regulation of broker and dealer activities of the specialists; and (3) regulation of members' transactions as dealers, other than as specialists. In each of these sections the method followed and the type of material presented are essentially the same. The chapter devoted to regulations of lending and borrowing activities of brokers may be used to illustrate the general plan of this work.

Some attention is first given to the historical development of restrictions on lending and borrowing activities of brokers beginning with the scanty material available for the period of crisis in 1907. The Hughes investigation, the work of the Pujo Committee, the developments of the twenties and early thirties, are briefly discussed as they relate to member borrowing and lending. The later regulations, imposed by the Federal Reserve Board and the New York Stock Exchange, are outlined and analyzed in much more detail and some of the reasons, real or merely apparent, are advanced for the various rules which became effective in the period 1934-40.

The second part of this section, outlining some of the quantitative materials available regarding member borrowing and lending, provides little new information. The final part of this section is a summary and appraisal which does contain some interesting points. The summary is of particular interest because the author has clearly indicated various conflicting aims which are embodied in the regulations, and he has marked out definite aspects of member borrowing and lending activities about which very little is known.

The other two main sections follow much the same pattern.

This volume does not present much that is new but it does bring together in clear, concise language the general framework of exchange member regulations and supplements what has been done in this field with well-selected materials drawn from many sources. The principal contribution is the emphasis on the conflicting aims of individual rules governing exchange members, on the need for clearly formulated policies, and on the need for much more factual information than has yet been secured.

FRANK P. SMITH

University of Rochester

Assekuranz-Jahrbuch. By S. J. LENGYEL, editor. 2 vols. (Basel: Verlag für Recht und Gesellschaft. 1941. Pp. 642; 540.)

This insurance yearbook, founded in the year 1880 by A. Ehrenzweig, is the oldest annual on this subject. Moreover, it is the most international publication of its kind, since it shows the statistical development in twenty different countries and contains besides an international bibliography of

private insurance in general, embracing all branches of insurance in twenty-three countries. Most of the space is devoted to new legislation, the second volume treating exclusively legislation in the United States during 1939 and 1940. It would be a great loss to insurance theory and practice all over the world if the sixtieth edition of the yearbook should be the last one, as seems possible. The present editor, formerly of Vienna, had to leave Europe and is now in Australia. Instead of being published in Austria as has been the case for the last fifty-nine years, it was necessary to publish this edition in Switzerland. Probably because of the characteristic difficulties of scientific publications within formerly independent European countries, the traditional first part of the yearbook containing scientific papers on insurance economics and administration has almost vanished. Should not America see that such an international publication survives?

ALFRED MANES

Public Control of Business; Public Administration; National Defense and War

Government Control of Business. By HAROLD D. KOONTZ. (Boston: Houghton Mifflin. 1941. Pp. xi, 937. $4.50.)

Government and the American Economy. By MERLE FAINSOD and LINCOLN GORDON. (New York: Norton. 1941. Pp. xvii, 863. $3.90.)

These two volumes represent substantial new additions to the growing list of texts for use in survey courses in "government and business." Although similar in general scope they differ considerably in approach, level of exposition, and emphasis. On the whole Professor Koontz's book is more conventional in approach, as is suggested by the title itself. In a brief introductory consideration of the problem of public control, he sketches the ebb and flow of governmental participation in economic life from early times, and describes the characteristic economic and legal institutions that constitute the setting of the contemporary problem of public control. The remaining seven parts of the book deal with government intervention in various segments of the economy, including transportation, public utilities, "private" business and trade, financial and exchange institutions, extractive industries, and labor. Consideration is given also to the promotional activities of government, and to the rôle of governmental enterprise. The book thus covers, in brief, the substance of a half-dozen upper class courses in sequence; the thread linking the several parts is that they each manifest, in one way or another, the common phenomenon of "government control."

In *Government and the American Economy* Professor Fainsod and Mr. Gordon have undertaken to survey an equally broad terrain. They, however, have organized their material in terms of the varying character, extent, and objectives of governmental intervention in the economic life of the community,

rather than in terms of a classification of "industries." They begin with an introductory description of the structure of the modern economy, and of the "political" organization of different economic groups, including business, labor and agriculture, emphasizing the rôle of these pressure groups in the functioning of modern government. The three remaining parts of the book deal, in turn, with government as a promoter of particular economic interests, government as regulator in the public interest, and public enterprise and conservation. Part III, dealing with government as regulator, covers substantially the same groupings of industries as are treated by Professor Koontz.

In this connection certain interesting differences in emphasis are apparent. Professor Koontz, for example, devotes nearly a third of his book (three hundred pages) to transportation and public utilities, business traditionally "affected with a public interest," and approximately half as much space to regulation to enforce competition and the control of specific industries such as coal and oil. Professor Fainsod and Mr. Gordon, on the other hand, place much less emphasis on transportation and public service industries, and much more on antitrust and trade practice legislation, the activities of trade associations, and our experience with N.R.A.

Especially interesting is the difference in emphasis accorded to the N.R.A. and subsequent experience. To Professor Koontz the N.R.A. was an "interesting, but happily short, experiment with the use of the code device for widespread business regulation," to be disposed of in two scant pages as an incident to the discussion of the control of competitive practices. Professor Fainsod and Mr. Gordon have treated it at very considerable length as a case study in industrial self-regulation under the aegis of government, and as such of permanent significance, quite apart from the situation that called it into being. Here, as elsewhere, they have brought into the foreground the grave problems of political organization and administration involved in any large-scale attempt at governmental control of or participation in the conduct of business.

Both volumes end with chapters that attempt an appraisal of the rising tide of governmental intervention in economic life, and of the possible alternatives of public policy. Professor Fainsod and Mr. Gordon are diverted, however, in the midst of their summing up, to a consideration of the impact of war upon the economy, and to a description of the measures for effecting the transition from peace to war. The treatment of the problem is brief, to say the least, in comparison with its contemporary significance, and gives the appearance of a hasty addition, not well integrated with the remainder of the book, or even with the general discussion of public policy, with which it is conjoined.

Both volumes have drawn heavily on the wealth of material made available in recent years through the publications of the T.N.E.C., the National Resources Committee, and other governmental and private sources. Both reflect, in considerable measure, the influence of the past decade of development in economic theory as applied to market phenomena and business behavior, although the employment of these tools has not been as thorough-

going as might be desired. Both stress the institutional developments of the past three-quarters of a century that have led to and conditioned the extension of governmental participation in economic life. Professor Fainsod and Mr. Gordon, however, have emphasized in greater measure the gradually increasing importance of newer objectives of public policy—the promotion of business recovery and stability, the attainment of a higher level of employment and national income—that have come to supplement the maintenance of equity as a basis for governmental intervention. They nevertheless have not undertaken to include in their discussion those monetary and fiscal measures by which also the government may seek to achieve these objectives. The relation of public works and other relief measures to economic recovery and stabilization is suggested, but the underlying theory is not expounded or subjected to critical analysis. Thus *Government and the American Economy* remains a partial treatment of the interrelations of government and the functioning economy; it could, indeed, scarcely be otherwise within the limits of a practicable book.

To the teacher in search of a textbook each of these volumes will appear to have points of strength and weakness. Professor Fainsod and Mr. Gordon have assumed the student to have a quite considerable background in recent American economic history and a familiarity with economic, political, and legal concepts and processes. They have almost completely eschewed definitions of terms except as these may be suggested by the context. This assumption that the reader will appreciate the full force of an allusion to industrial unionism, the injunctive process, or the English common law undoubtedly contributes to an easy and perhaps flattering style, inasmuch as there is no appearance of writing down to the level of the uninitiated. Nevertheless it may make many passages appear cryptic to many students, and doubtless will put on the teacher a considerable burden of supplementary exposition. And one need scarcely be a pedant to wince at the recurring use of nouns in such Teutonic adjectival combinations as "pre-World War I British industry." Professor Koontz, by contrast, assumes relatively little prior equipment on the part of the student, and endeavors to supply the relevant background himself. Although his book as a consequence seems more "textbookish," his careful, clear and systematic treatment is far from devoid of reader interest.

These volumes, formidable in length as they are, nevertheless still involve in considerable measure the inevitable sacrifice of depth of analysis in the attempt to cover a broad range in a single text. Much space must necessarily be devoted to the enormous mass of legislation and machinery through which governmental control is articulated, and little room remains for the detailed presentation or critical analysis of specific problems. In Professor Koontz's volume, for example, the patent question is disposed of in a half-dozen scattered pages, as are also the economic and legal aspects of resale price maintenance; the open price system and the basing point system are accorded four pages each. Substantially similar in extent is the coverage of these representative issues in Professor Fainsod's and Mr. Gordon's volume.

Despite the inherent difficulties of any such attempt at broad coverage this reviewer has been impressed by the very considerable amount of detail

that the authors of both volumes have been able to include in their panoramas without sacrificing general perspective or becoming mere cataloguers of facts. It is difficult to see how much more could have been accomplished within the limits of available space.

Princeton University

Industrial Organization; Business Methods and Policies

Top-Management Organization and Control. A Research Study of the Management Policies and Practices of Thirty-one Leading Industrial Corporations. By Paul E. Holden, Lounsbury S. Fish and Hubert L. Smith. Conducted under the auspices of the Graduate School of Business, Stanford University. (Stanford University: Stanford Univ. Press. 1941. Pp. xvii, 239. $4.00.)

One cannot appraise this book without giving careful consideration, at the outset, to the special circumstances under which it was written. Essentially, it is a report upon a comprehensive and ambitious research project on the business practices of modern American corporations. The value and the limitations of this study are strictly circumscribed by the special plan under which it was developed. Its findings will be of interest to those concerned with the technical structure of American management, but will be of limited value to those persons who desire to know how business men reach decisions on those vital issues concerning labor, the federal government, the public, and industry generally.

In the Preface, the Dean of the Business School of Stanford University states that "after several months of study and discussion, during which time leading executives joined with members of the Business School faculty about the conference table, a broad program was formulated and the project undertaken." It was conceived that this would not be an "academic" study, but would realistically show ". . . how policies are formed, how authority is delegated, how control is effected, how departmental or divisional points of view are harmonized, how results are measured, how extravagant practices are corrected, and how waste is eliminated."

A group of thirty-one "nationally known well-recognized industrial companies were chosen" for study and some of the companies assisted in the financing of the project. Data sheets were designed to gather information which would give "comprehensiveness and comparability." The field work for the collection of the data required over seven months and an additional six months were required to "analyze and coördinate the vast amount of material obtained." The report relates to American big business. The thirty-one corporations studied had assets of over 8 billion dollars, or an average of about 260 million dollars per company. They were largely industrial, banks, merchandising organizations, public utilities, and railroads being omitted.

The research project was carried on under at least three important limitations, which are stated in the Preface, and a clear recognition of them is indispensable to an understanding of the book. These limitations—the anonymity of the corporations and their practices, the absence of any discussion of the factor of personality, and the indisposition to evaluate or criticize—obviously place a great barrier to a realistic approach of the manner in which American industry is directed.

It was further assumed that the basic facts relating to American management policies and practices could be ascertained exclusively from the data gathered by the research project. This apparently is the reason why one finds no reference at any point, either in the text itself or in the appendix, to any of the mass of literature relative to this general subject which has accumulated in the government and in schools of business and social science.

"Top-management" is variously defined in the book. It means, essentially, the central management of modern American corporations through the board of directors, the officers who actively direct the corporation, and finally the departmental heads of the various branches who carry out its work on a day-to-day basis.

A specific illustration of the inherent difficulties under which the report was made is found in a consideration of the function of the board of directors. On page 17 we find the following statement: "The point of view of the board of directors must . . . be identical with that of the stockholders. . . . In fact the fundamental concepts of the first zone or level of management (the directors) is management for the benefit of those who own the business." This is a clear statement of the classical, and normally accepted, obligation of directors to stockholders. But the authors go on to point out that "this point of view is not always easily maintained. Many directors are also full-time executives whose interests as members of management may momentarily be at variance with those of the stockholders."

Following the identification of this general problem, it might be expected that some conclusion would be drawn from the experience of the corporations in question. No opinion whatever is expressed on this vital point. In fact, the remainder of the material regarding the board of directors is primarily devoted to a discussion of the mechanics of its organization and the board's relations with the managing officers in the corporations. Nowhere is there even a hint that the present organization of, and control exercised by, the board of directors of any one of the thirty-one corporations is ever at variance with the interest of stockholders.

The second zone of "top-management," as outlined in the volume, is that of the "general management or administrative function." This general management is in the hands of those persons, largely company officers such as vice presidents, who exercise ". . . an active and continuous function involving the initiation, formulation, coördination, and development of . . . proposals and results." Here one finds considerable material which would prove helpful to those interested in the technique of structure and organization.

It is at this level of management that the major policies of the corporation are outlined, and the major decisions regarding them put into effect. However,

because of the inherent limitations of the project outlined above, one again notes the lack of what might be termed a realistic approach to the problem. Management is made up of men, acting alone or in unison. Their business decisions are not reached in a business vacuum but under concrete and specific circumstances. One of the stated objectives of the book is to ascertain "how policies are formed." This objective has not been reached.

The third zone of "top-management" is seen as the "divisional—or departmental-management function." The definition of the function and responsibilities of the managers in this third zone, with the description of their organization and control, is one of the best features of the report, primarily because it is in this zone that the day-to-day business work is done. Here are carried out the policies which have already been established either by general management or by the board of directors. The limitations inherent in the project, as discussed above, are least confining at this juncture.

Following its description of the structure of the three zones of management, the book discusses at considerable length the types of controls exercised by "top-management" over the various functions of the corporations, for example, the practices followed in the control over costs and capital expenditures. In addition to discussion of these familiar techniques of control, there are sections of special interest devoted to the controls over organization, research, line of products, and other aspects of the operations of modern corporations, including an interesting account of "Control Over Demands Upon Executive Time" (Part C, Section 16).

The report fails to consider adequately four of the most vital problems confronting American business: its relations with labor, with the industry in which it operates, with the government, and with the public generally. One is surprised to find, for example, that in the Index there is no reference at any point to labor or to unionization. On pages 130-141 there is a section (Part C, Section 6), entitled "Control Over Wages," with a detailed discussion of wage policies, job evaluation procedure, and control procedure as evolved by management. But at no point here is there any reference to the rôle which organized labor now plays in the establishment of wages. It is interesting to speculate on what the treatment of the wage problem would have been if the Business School had made this part of the study in coöperation with organized labor, rather than with business. The absence of any realistic treatment of the problem of wages is emphasized by the fact that there is no discussion of the relation of the corporation to organized labor. This is surprising in view of the fact that the locale of the corporations studied is largely the Pacific Coast which has been, for the last ten or twenty years, the focal point of a bitter feud between labor and capital.

The discussion of "Control Over External Relations," (Part C, Section 14), leaves the reader in somewhat of a quandary. The authors admit that "it is unfortunate that business in general has delayed so long the public presentation of its case, collectively and individually." Following this, two pages are devoted to the public relations activities of the thirty-one corporations. Most of the discussion is taken up by the quoted statement of one company regarding its attitude toward this important work. From this scanty material, the

reader is, of course, at a loss to know what, if anything, these corporations have done in this field.

In the same section there is a discussion, fourteen lines in length, of the relationship existing between the corporations and the respective industries in which they operate. It is stated that "most of the companies give positive endorsement to the collective study of common problems." In view of the importance today of the relationship of a company to its industry through trade associations, and the associated legal and legislative problems, this material is extremely skimpy.

As to the material regarding the relations of the thirty-one corporations to the federal government, it is to be noted that the study was begun in 1939, five years after the advent of the New Deal with its innumerable plans and programs for an extension of the power of government over private enterprise. Certainly these corporations must have taken action in this field meriting a consideration greater than the half page it is given.

These are some of the reasons why a student twenty years from now would find this volume of little assistance in illuminating the general picture of how American business actually operated in 1940.

Top-Management Organization and Control is a research study in the right direction. Stockholders, corporate officials, salaried employees, wage earners, the government, and the public all want more information from reliable sources about modern corporate enterprise. A beginning has been made in this study, but the emphasis has been given almost entirely to the mechanics of the management's structure. The result is a tentative blueprint of corporate organization and control.

The next step, and a much more difficult one, is to obtain the data, as far as possible, on how the structure actually functions. This material, in the opinion of the reviewer, can best be gathered by inquiring into how actual business decisions are made with respect to certain concrete and specific problems. A study along this line would feature the action of men, rather than the static outlines of corporate organization.

JOHN E. DALTON

New York

Mining; Manufacturing; Construction

The Automobile Industry. By E. D. KENNEDY. (New York: Reynal and Hitchcock. 1941. Pp. 333. $3.50.)

This popular account of the "coming of age of capitalism's favorite child" is by no means a scientific study in economic history or industrial organization; it sets out simply to sketch, in an interesting way, the beginnings of the motor industry and its progressive expansion to a predominant position in American economic and social life. The author has given a year-by-year, almost blow-by-blow account of the fortunes of the automobile producers, including many whose names come back like ghosts out of the past.

Although he has not essayed a scientific study of the industry, Mr. Kennedy nevertheless finds in its record, as compared with those of many other major industries, a striking contrast. During the past two decades, especially, there has been an increasing concentration in the industry, brought about, not through the merger of rival concerns, but simply through the failure and disappearance of independent manufacturers, many of which had, during the 1920's, been substantial and profitable enterprises. Thus, paradoxically, the automobile industry is today more completely dominated by the big three than is the steel industry by its major producers, yet the major motor producers have reached their position of dominance not through combination, but through progressive expansion of their sales relative to the entire volume. The end result is nevertheless the same: a situation in which price competition does not appeal to any of the major rivals as "good business," and in which the independents continue an ever more precarious existence.

Mr. Kennedy has been content to pose his paradox for the reader, without attempting an economic interpretation of the industrial history he has recounted. Indeed he points to the rise of Chrysler, under circumstances that seemed to spell inevitable failure, as an indication that the outcome was not a mere product of impersonal forces. But even though one assumes that the mortality of the independents was due to their failure to "have what it takes" in a period when the demand for automobiles as a whole was no longer rapidly expanding, one cannot help wishing that Mr. Kennedy had gone further in supplying economic answers to the question that he raises. Nor does the reader who is inclined to speculate find the book a very helpful source of information with which to proceed. For although it is studded with figures as to annual sales and profits, the data presented are not systematically organized or sufficiently inclusive to support further analysis without recourse to other sources of information.

Princeton University

The Iron and Steel Industry in South Africa. By C. S. Richards. (Johannesburg: Witwatersrand Univ. Press. London: Lund Humphries. 1940. Pp. lxi, 471. 25*s*.)

This work is an appraisement of the operations and pricing policies of the South African Iron and Steel Corporation during the period of five years after it began production in 1934. Incidentally it outlines the history of the whole industry in South Africa and describes the foreign sources of supply. "Iscor," the popular name of the Corporation, is a quasi-public enterprise which was organized by the Union government and financed to the extent of 90 per cent of its capital. During the period studied it controlled 92 per cent of the capacity for the production of basic iron and steel in South Africa. This was barely one-third of the domestic consumption, the remainder having to be imported mostly from Europe, with small amounts from the United States and occasionally from Australia. (This was the situation until September, 1939. What has happened since is an unwritten chapter.) Before 1934 some

97 per cent of the consumption of basic iron and steel in South Africa was imported, a considerable amount coming in the form of scrap used by domestic fabricators. Earlier experiments had indicated that ferrous products of standard quality could be produced in South Africa at a mill cost as low as that of the foreign mills, and thus would require no tariff protection. South Africa was an excellent nursery for the "infant industry."

The real owner of Iscor, the Union government, determines the tariff rates on iron and steel, and makes and administers the dumping laws; owning the railroads, it fixes the freight rates on iron and steel both inward and outward, and, strange to say, it aided Iscor to enter the European cartel although this raised the price of steel to South African consumers to the benefit of foreign producers. It has used all these means to make Iscor profitable, and it has been.

Iscor follows a basing point plan of a peculiar sort, the base price being the cost of foreign steel laid down at the ports of entry. As Pretoria, where the mills are located, is a non-basing point hundreds of miles from the coast, phantom freight is paid on most of the shipments. The largest monopoly-taxed buyer is the gold mining industry, which is located near Pretoria. Doubtless next in order is agriculture. These two are almost the only exporting industries.

The author is professor of economics in the University of the Witwatersrand and is one of the editors of the *South African Journal of Economics*. His work is a model of scholarly research into the problems of a very complicated situation. South Africa has been made a veritable laboratory of economic experimentation, and offers lessons of international import to students of infant industries, protective tariffs, international cartels, state socialism, and national planning. Even the discouraged liberal will be cheered by finding some awful object lessons which he may use to point a lesson.

Labor and Industrial Relations

Union Policies and Industrial Management. By SUMNER H. SLICHTER. (Washington: Brookings Institution. 1941. Pp. xiv, 597. $3.50.)

For many years there has been a shadow-land in the precise knowledge of certain aspects of labor relations. A good deal of hearsay, a few competent but fragmentary studies, and occasional rule-of-thumb observation has been the limit of the intellectual property of most labor economists in so far as the shadow-land is concerned. This misty territory has been that which encompassed the policies and plans whereby unions have sought to influence the entrance of new artisans to a trade, to control the system of apprenticeship, to influence the hiring and lay-off policies of employers, and to meet the problems of technological unemployment. The principal reason for the comparative dearth of systematic knowledge of these subjects has probably been

the enormous variety of policies involved, the deviations in practice from established rules, and the obvious difficulty of canvassing the facts of thousands of local situations. A single and comprehensive treatise on the subject had seemed virtually impossible. In the book under review, however, Professor Slichter has accomplished this most difficult task. He has accumulated and used an incredible amount of factual information, and to this he has applied a sound knowledge of economic theory and a generous portion of plain human wisdom. The results are, of course, not perfection; but they are little short of astounding. I have no hestitation in asserting that this book became the classic treatise in its field on the day of publication.

Professor Slichter has made good use of those fragmentary studies which preceded him, and to these he has added the results of a vast amount of original investigation. In his chapters on technological change, he has carried on and developed the justly famous pioneering of George E. Barnett. He has classified and organized a considerable volume of information on union attitudes toward labor-saving machinery, has analyzed these attitudes from a stable basis of economic theory, and has incidentally included a good portion of interesting labor history. Equally well, he has developed the early work of D. A. McCabe on piecework and timework, adding to those good but rudimentary studies an extensive array of up-to-date material. But in his chapters on union control of hiring and lay-offs, and on the control of cost differentials between union and non-union establishments, Professor Slichter has earned pioneering fame for himself. A careful collection of facts in research areas which have been greatly neglected, coupled with a splendid demonstration of the author's marked ability to classify facts, comprise a distinguished contribution to the knowledge of labor economics.

Unfortunately, the standard of quality varies from place to place in the book. For example, the chapters mentioned in the preceding paragraph maintain a high level, excepting for a few sections which appear not to be fully digested nor clearly expressed, and which therefore strike the reader with a mild shock. The discussion of union-controlled hiring halls, as an illustration, begins with the implication that such halls are "almost certain" to lead to discrimination, favoritism, and internal politics. A page is devoted to the longshoremen's hiring halls on the West Coast, but no reference is made to the elaborate "plug-board" device whereby the union has sought to eliminate all possibility of favoritism and politics. Since these West Coast halls are admittedly of sufficient importance to warrant brief description in his book, it is reasonable to expect that they would have been mentioned as an exception to the general rule of favoritism which the author has enunciated.

Further, there is given no hint of the favoritism and politics which prevailed before the union hiring hall was established. As a matter of fact, the union's insistence upon controlling the hall (at the time of the 1934 strike) was the product of its determination to eliminate the graft and favoritism which had dominated the waterfront for a dozen years. The old "shape-up" system was intolerably corrupt and the longshoremen themselves were driven by necessity to abolish it. The seamen, likewise, sought union control of the hiring hall in order to eliminate the petty graft and incompetent favoritism

of the landlubber staff of the employers' hiring hall. I doubt if any union-controlled hiring hall has exceeded, in its massing of small-scale graft and politics, that notorious agency, which I described in this *Review* in June of 1935. Dr. Slichter's condemnation of union hiring halls is not adequate unless they are shown to be worse than reasonable alternatives. And this he has not shown. He mentions with approval the growth of government operated employment services, but does not discuss their potentialities, nor offer them as a general substitute. I still agree with Professor Slichter, however, in his broad conclusions on this subject, including his preference for public employment offices. Further, I cannot really contest any single statement in his discussion. Rather do I feel that misleading implications have crept into the text, apparently as a result of incomplete research or hasty analysis. The weight of this criticism, of course, is greatly mitigated when the vast scope of the work is recalled. No one can expect him to include everything.

The last third of the book is devoted to the major experiences with union-management coöperation, and includes studies of the women's garment industry in Cleveland, and the development of such coöperation on the railroads, by the Amalgamated Clothing Workers, and in the Naumkeag Steam Cotton Company. In all of these chapters there is evidence of a vast amount of original and competent research. In the chapters on the railroads, however, it is noticeable that no reference is made to the substantial work of Louis A. Wood. This is unfortunate, since Professor Wood is entitled to credit for his ground-breaking in this field, a piece of work fully as important as that of R. C. Nyman on the Naumkeag experiment, work which does receive due credit from Professor Slichter.

In drawing conclusions from his description of the four examples of union-management coöperation, the author presents an unexcelled analysis of the reasons why the device has spread so slowly, pointing out, among other reasons, the significant extent to which employers have been responsible for this lethargy. But then, apparently forgetting this opposition by employers which he has just expounded, he expresses his belief that union-management coöperation will spread more rapidly in the future because of the changed needs and attitudes of the unions. I agree with Dr. Slichter that the attitudes of unions are undergoing great changes, but I am not so optimistic as he in his apparent assumption that employer opposition is also vanishing. There are certain outstanding illustrations of business men who are really eager to deal in a business way with unions, as exemplified by Mr. William Batt, of SKF industries, in the Town Meeting of the Air last November. But I feel sure that a large proportion of America's business men are yet unconvinced, and will probably remain so for some time.

There is a further point which should be mentioned. Professor Slichter assumes that union-management coöperation will be the normal mode of organizational procedure when employer-employee relations "come of age" —when a fully developed "system of industrial jurisprudence" has emerged. The doctrine that such coöperation is an attempt at "class collaboration" and is therefore impossible (except in isolated instances) is of course a part of the Communist credo. But this doctrine is not necessarily invalid simply

because of its political affiliations. I have not read any exhaustive study of this doctrine, nor have I attempted to think it through myself. Therefore I am not prepared to state categorically that union-management coöperation is *the* form of the future, or that, on the other hand, it is the will-o'-the-wisp of hopeful but futile liberalism. Perhaps because I am disappointed that Professor Slichter did not think out this problem for me, I regret that he assumed the first alternative. But I do think that the second alternative should at least have been mentioned as a possibility. Throughout his chapters on the subject, there are indications of his awareness of the question, and frequently there are data which bear upon it. But the problem itself receives no special attention.

An important contribution made by the book is the result of the attention which it gives to the unwritten rules and traditions of certain trades and industries. The ignorance on the part of an arbitrator of such occupational peculiarities has resulted in the failure of many arbitrations. And the ignorance on the part of union men of the necessity for altering obsolete traditions has caused the decline, and sometimes the dissolution, of many unions. Professor Slichter has given us valuable information on many such traditions, information of great value to arbitrators, mediators, employers, and union men as well as to academic students. For this reason, among others, the book should be widely read and frequently used. During the trying times through which the United States is struggling, the book is pertinent and of immediate practical value, and should not be overlooked by anyone concerned with labor relations. When democracy itself is in peril, it is necessary to develop and strengthen the procedures of industrial democracy. This book, besides being a treatise on technical matters, is an inspiring essay on the potentialities of democracy.

The entire volume is excellently organized, so that, in addition to being good reading, it is readily usable for reference. The format is standard Brookings, the typography excellent. A good index, coupled with a detailed Table of Contents, provides ready access to the materials within the book. Dr. Edwin G. Nourse introduces the volume with a brief but graceful and relevant Preface.

Stanford University

Labor Cases and Materials; Readings on the Relation of Government to Labor. By CARL RAUSHENBUSH and EMANUEL STEIN, editors. (New York: Crofts. 1941. Pp. xvi, 674. $4.00.)

The Development of Labor Relations Law. By WAYNE L. MCNAUGHTON. (Washington: American Council on Public Affairs. 1941. Pp. 197. $3.00, cloth; $2.50, paper.)

Labor Cases and Materials will join Commons and Andrews as a standard reference work for the student of labor law. The book presents in an orderly classification the major pieces of labor legislation of the federal government and the states, together with the related decisions of the courts concerning

the constitutionality and the application of these statutes. Some of the important common law rulings of the courts affecting the legality of the objects and methods of American trade unionism are also included.

In many instances the laws are reprinted in their statutory form, save for minor editing and omissions. Descriptive summaries by the editors are also included where they are helpful as background material. The cases themselves are transcribed directly, in order to furnish the reader with the actual reasoning of the court in its original form. Where important dissenting opinions were involved, as for instance in *Morehead v. New York ex rel. Tipaldo,* where Mr. Justice Stone offered a vigorous criticism of the majority reasoning, the authors have made available the argument of the minority justices. Since many of the decisions of the Supreme Court in recent years were presaged in dissenting opinions of earlier years, the inclusion of these differences in judicial opinion is very valuable for the reader.

The material of the book has been divided into two major sections: one which is termed "Governmental Influences on Collective Bargaining," and the other "Government and the Labor Contract." Under the first topic, which was the work of Mr. Raushenbush, there are presented these subjects: picketing and intimidation, criminal syndicalism, laws affecting assembly and picketing, boycotts, the closed shop, mediation and arbitration, and the National Labor Relations act.

In the second topic, prepared by Mr. Stein, the material has been classified under these heads: regulation of labor supply, wages and hours laws, regulation of working conditions, workmen's and unemployment compensation, and old-age assistance and benefits.

Perhaps the greatest value of the book is that it gathers together conveniently a great number of important acts of legislation and related court decisions. Any teacher of labor law will perceive the advantages which this procedure affords. And if he is an exponent of the case method, as the authors declare themselves to be, he will possess in this work an indispensable teaching vehicle, since the student is given the primary materials of labor law for his own analysis and evaluation. This does much to replace the use of commentaries and secondary sources as a basis for course instruction.

In addition to presenting the sort of subject matter one might ordinarily expect to find in a book of this character, the authors have made some noteworthy additions. Thus the chapter dealing with mediation and arbitration contains a section on the limitations confronting unions in war and defense industries, in which the procedure of the First World War is set forth, along with some current issues and problems. In the chapter entitled, "The Borders of Violence," there is included considerable important historical material concerning industrial conflicts, along with related court decisions bearing on such disputes. Moreover, in the chapter on free speech and unionism, there are to be found the important decisions of the U. S. Supreme Court in the de Jonge and Hague cases, dealing with criminal syndicalism and with laws and administrative actions which affect the right of assembly. In the discussion of the National Labor Relations act, the authors have included an analysis of the bargaining unit problem, joining to it the decisions of the Court in

the International Association of Machinists and the Pittsburgh Plate Glass cases. Finally, in the chapter on the minimum wage, there is included a section on the Fair Labor Standards act, in which direct excerpts from the statute, as well as decisions of the Court in the Darby Lumber and Opp Mills cases, are to be found.

The material is well classified and carefully indexed. There is a useful analytical table of contents, a bibliography that is broken down by chapter headings, a table of cases with related page references, and the usual subject index. The result is a work of careful scholarship and considerable usefulness.

Dr. McNaughton's study, entitled *The Development of Labor Relations Law,* represents an attempt at an analytical and genealogical treatment of the changes which have occurred in this field of law during the thirties. The center of interest is the labor bargain and the rights of unions and of management in matters of labor relations policy. The contents are arranged for "the student of business rather than . . . the lawyer." The result is not a very original treatment of the problem, which is probably partially dictated by the author's decision to cover the field—a vast field, at that—rather than to deal intensively with a narrower and more workable sector.

Dr. McNaughton believes that labor relations law is a function of the forces of three distinct interest-groups: employers, employees, and what he terms "society as a whole." The simplicity of this breakdown, together with the author's judgment that laws such as the National Labor Relations act ". . . can remain in force only so long as public opinion tolerates them," may be questioned. Public opinion is a rather tenuous concept, and it is a long and risky step to assume that it stands in a direct and precise relationship to legislatures and their activities. Political power is just not that evenly diffused in our society.

The treatment of laws developed to protect the interests of employers is centered on an examination of the legal status of the different tactics used by employers to strengthen their bargaining power. These tactics include "positive" efforts to strengthen the market position of employers, and "negative" efforts to weaken the bargaining status of the sellers of labor power. The same formal treatment is then applied to the activities of employees. Each tactic in the bargaining struggle is analyzed in terms of statutory enactments and common law decisions, in order that its legal status may be determined. In his findings and conclusions, the author has relied heavily upon what the courts have said, and upon what other students think about what the courts have said. The result is that there is very little original evaluation either of specific trends or of instances of reasoning.

G. H. HILDEBRAND, JR.

University of Texas

Occupational Mobility: Democratic Efficiency through the Use of Human Resources. By OMAR PANCOAST, JR. (New York: Columbia Univ. Press. 1941. Pp. viii, 155. $1.75.)

The author describes an ambitious, threefold purpose: to publish a doctoral

dissertation; to popularize a course of political and social action; and to demonstrate an application of economic theory in terms that a layman can understand. The first of these is obviously accomplished.

There are eight chapters. The first poses the question: Can democratic methods employ our human resources effectively? Four chapters then summarize historic and current economic points of view toward labor mobility and the allocation of labor power in modern society. In chapter VI, the author outlines his own proposal and indicates how labor can be properly distributed within the framework of a democratic society. Chapters VII and VIII present the author's answer to some of the questions raised by his proposal and summarize his final conclusions.

The study seeks "to develop a line of consistent thinking, on the basis of which we could build a sound policy of labor allocation" (pp. 8-9). The author believes that "it justifies a renewal of faith in the decentralized, individualistic method of running our economic affairs" (p. 10). Economic consideration of labor allocation up to this time has been largely concerned with the possible relationship between wage adjustments and employment. Argument has centered on the probable elasticity of demand for specific types of workers, as, for instance, those in the building trades. Mr. Keynes has, however, pointed to one weakness in such analysis in its tendency to ignore the essential interrelationship of distributional and productive aspects of an economy, *e.g.*, the effects of increased shares of income for certain groups on savings and consumption. "It is left to the present writer to apply the newer methods of analysis (especially the Keynesian framework) to tracing the actual steps by which mobility might be expected to improve employment and general economic efficiency" (p. 106), and to demonstrate the effectiveness of a reduction of wage differentials, as distinguished from the Keynesian concept of a universal and proportionate decrease of all wages.

The author's proposal is, then, that society facilitate, by special training and/or whatever means appear likely to be effective, the movement of workers from lower paid into higher paid occupations. The first contemplated result will be a reduction in earnings differentials as earnings of lower paid workers rise and those of higher paid workers decline. The shift will increase the propensity to consume on the part of workers involved and the public. Opportunities for capital investment will be increased, and business morale will be maintained at a high level. The social cost of retraining and facilitating such shifts would be generously compensated by the improved employment situation. Indeed, this program is essential, for now "the better opportunities to make a living [are] preëmpted by a few groups" and "the lack of buying power in the rest of the population condemns even this privileged fraction to a decreasing market for what they sell and higher costs for what they buy" (p. 135).

Laymen may be more impressed with this line of argument than can be expected of those who have had occasion to study labor markets. For it involves a subtle but possibly important confusion of wage rates and earnings and some highly significant questions as to the elasticity of demand for various types of labor and for the products of that labor. Thus when workers

shift from low to higher paid occupations, it appears likely that (1) wage rates in the high level occupation will fall, and (2) wage rates in the lower level occupation will rise. But whether earnings will rise in either case depends on the elasticity of demand in these markets. That cannot be measured by assumptions, particularly questionable ones such as that demand is "notoriously inelastic" in extractive industries (pp. 109 and 136). Nor is it so simple that "at the worst, we might set statisticians to discover the areas where such conditions prevail" (p. 111). The point is, as the author cleverly and effectively demonstrated in his chapter III, that almost nothing is known as to the elasticity of demand for labor in specific markets. Until factual knowledge is available, demonstrations such as this can be presented only as hypotheses rather than conclusions.

The hypothesis thus stated is, however, intriguing and worthy of careful study. Only empirical investigation of specific labor markets can provide a factual basis for appraising its practical value.

DALE YODER

University of Minnesota

Economics of Labor. By RICHARD A. LESTER (New York: Macmillan. 1941. Pp. xv, 913. $3.75.)

In many American colleges and universities the study of labor problems is either omitted entirely or treated as a shabby and unwanted visiting relation by the reputable members of the economics family. The explanation is multiple. But I suspect that one factor is the failure on the part of students of labor to master and use the organon of theory which is central in most serious work in the subject. This failure is apparent in the textbooks available for college courses in labor problems. There is the familiar description of the social and political trends influencing labor history. There are the position of trade union organization and the techniques used by them to improve the welfare of members. There is ordinarily but an incidental and apologetic use of theory, and a corresponding inattention to certain economic problems that require theory if they are to be studied at all. It is frequently difficult to decide whether the result is a book in economics or not.

Mr. Lester writes as an economist, determined to employ the analytical instruments of the economist in his study of the problems of labor. Let it be said at once that he has carried out his determination with persistence and skill.

Over one-half of his long book is devoted to "Labor's Economic Problems": wages, income, employment, hours, relief, old-age, accidents and the rest. Each is analyzed with the full kit of the economist's tools at hand. The emphasis is ever upon the problems as derived from and affected by the market situation. More arresting still is the inclusion in his tool-kit of those shining instruments of monopolistic-competition and savings-investment-income theory, which are the outstanding contributions of the last half-century.

His was no easy task. As he would perhaps be the first to admit, it requires doing again and again if the most effective way of presenting a difficult and

subtle material is to be found. The several chapters on wages and employment rest on an extensive body of literature in price and income theory. They should help the hard-working student to a deeper understanding of the problems than can be won in any other way. But the inherent difficulties are so great that I doubt whether most undergraduates, as now prepared, can surmount them successfully. If they are to do so, they must first of all gain a firm elementary grasp of contemporary price theory. A course in monetary or income theory would also prove highly desirable. Otherwise, Mr. Lester's writing will be very refractory indeed, for all the fact that it is in my opinion well done, and sound in its general directives.

Consistent with his theoretical chapters, Lester has included a set of studies of specific market situations in which labor organization has grown: transportation, coal, clothing, steel, newspapers. They run in terms of the effect of the economics of the industries upon labor relations, and are excellent. Teachers can readily expand this section at will, by similar forays into other organized fields. Students should gain rich insight into the rationale of union techniques, their limitations, and the consequences of their use on the welfare of union members, of workers outside their ranks, and the economy as a whole. By continuous reference to the theory previously discussed, Lester evokes an enviable unity of presentation.

His emphasis upon principles is at the expense of emphasis on facts as such. This is no loss, for, as he says in his preface, "facts mean little until they are examined and interpreted." The teacher can easily supplement Lester by referring students to the abundant factual data in newspapers, magazines, and private or public reports.

Some readers will consider his chapters on labor organizations, employer attitudes, and government intervention inadequate. In my opinion, Lester might well have emphasized more than he has the National Labor Relations act, the forces that so dramatically led to its adoption, and the subsequent work of the National Labor Relations Board. The political aspects of the labor movement and the baffling problems of dual unionism could thus have been brought into higher relief. These deficiencies can, however, be repaired.

The book will win approval on its central distinction: emphasis on theory, the market, and contemporary price and income analysis. For graduate students it is an excellent manual. For undergraduates I hope it may soon become so as teachers coöperate by giving students more adequate training before permitting them to tackle some of the most difficult problems in the entire field of economics.

J. Raymond Walsh

Williams College

Stabilizing Jobs and Wages through Better Business Management. By Herman Feldman. (New York: Harper. 1940. Pp. xv, 334. $3.50.)

Dean Feldman's name is well known as a student and proponent of plans for the regularization of employment and income. The present volume is a welcome addition to his earlier work in this field. It is his conviction that

in spite of the many factors operating to produce job insecurity, the efforts of pioneering firms have demonstrated that much can be done to produce a greater degree of regularity in work and wages. A persistent purpose, imagination and appropriate methods on the part of management can, he believes, accomplish this result. He sets out, by reference to the experience of over a hundred firms, to stimulate the imagination and suggest the methods.

This is the primary utility of the book. It is a handbook of possibilities in the field of employment regularization which demonstrates the inventiveness of American management and which, at the same time, describes their efforts in enough detail to provide stimulus for those who lack such inventiveness.

Systematically he discusses the various possibilities: market research and distribution planning, diversification and simplification of product, market controls, balancing the work schedule, planning and administering technological change, personnel practices, wage payment stabilization, seniority provisions, interplant coöperation, and other devices. Each area of effort is described in detail, the advantages, disadvantages, and problems of each are explored. The latter includes an exploration of the issues raised by the necessity of administering such projects in an era of industrial relations thoroughly modified by new developments in labor organization and social legislation.

This is enough for one book and a major contribution to thought. One hopes, however, that the author will continue his work in this field and give us eventually a comparative study of the experiments which failed, as well as of those which had some measure of success, in order that we may understand the factors which make for succeess and failure in such attempts. In the present work, Feldman has given a stimulating account of the alternative means of accomplishing a desirable and increasingly important objective. For the most part he leaves to management the task of learning by trial and error the adaptability of these means to their own circumstances. Ultimately, of course, that must be done. But a more thoroughgoing analysis of the factors making for success or failure would make that adaptation less open to error.

E. Wight Bakke

Yale University

Social Insurance; Relief; Pensions; Public Welfare

Economics of Social Security. By Seymour E. Harris. (New York: McGraw-Hill. 1941. Pp. 455. $5.00.)

This study might be termed an approach to some basic aspects and problems of the American social security program from the point of view of modern economic theory. The author is not interested in social security as an institution to improve the lot of its beneficiaries, but in its effects upon the volume and fluctuations of output and employment in the economy as a whole. It is a study addressed to the students of banking and monetary theory, fiscal

policy, and economic fluctuations, at least as much as to people who are interested in social security for its own sake.

This book is dedicated to J. M. Keynes. The author is a Keynesian, but not a slavish follower of Keynes. He is most appropriately described as an economist who brings to bear on the problems he considers all major recent developments in economic theory. He avoids unsupported assertions; instead, he carefully analyzes his problems and logically develops his conclusions. At the same time, he fairly presents arguments and points of view with which he does not agree. His treatment is scholarly and convincing throughout.

There are three parts to this study: the relation of the social security program to output, questions of finance and reserves, and the incidence and effects of payroll taxes. All are brought together in an opening summary chapter, followed by a more extended discussion of some of the practical applications of the author's conclusions. Briefer summaries occur at the end of the treatment of each major subject. These are the parts of the book in which general readers will be most interested, but students of economic theory will get most out of the carefully reasoned discussion upon which the conclusions are based.

In Part I, the first question considered is that of the deflationary effects of the reserves in the social security program. The author concludes that on this issue no decisive answer is possible. The social security taxes, which then went almost entirely into reserves, were a factor in bringing on the depression of 1937-38. Other factors, however, were more important, and if all social security receipts and payments are taken into consideration, there was a large net contribution to spending by the Treasury.

Next, the author discusses the effects of the social security program on savings, consumption, prices, and output. These effects will vary with methods of financing, the degree of employment of the factors of production, the extent of their mobility, the propensity to save, the rate of investment, and still other variables. Any attempt to give dogmatic answers to the many theoretical questions which arise at this point is unscientific.

The final subject discussed in Part I is that of the investment of the social security funds. It was this problem which attracted the author to the comprehensive study of the economics of social security which he has undertaken. His conclusion on this subject is that "on the whole, the system in operation seems to be the most acceptable one."

The discussion in Part II, "Finances and Reserves," centers around the controversy over reserves in the old-age insurance system which raged so furiously prior to the Social Security Act Amendments of 1939. The general conclusion is that, while the 1939 amendments helped to allay opposition to the program, they, unfortunately, were supported by untenable arguments which may have serious consequences in future years. The 1935 law did not provide for full reserve financing, and the reserve by 1980 would almost certainly have been smaller than $47,000,000,000. "Pay-as-you-go" as used in this controversy is a most inappropriate term, as it is really deficit financing, with no provisions for meeting the cash deficits when they arise. "There is a real danger of the non-fulfillment of promised benefits in the later years" and

an absolute certainty that very greatly increased taxes will be necessary to meet the increasing obligations for promised benefits. In view of this situation, the reduction in the taxes of the next three years, made in the 1939 amendments, was a mistake. While the $1,000,000,000 of revenue which will be lost by reason of this tax reduction does not bulk large in comparison with the total of the taxes which are expected to be collected in the next few generations for old-age insurance purposes, it is ominous that this needed revenue was lost "at the first signs of pressure." The mistake made is the more tragic because, within a few months, we had to launch our great defense effort, in which concern about the alleged deflationary effects of the social security taxes has been superseded by anxiety about inflationary price rises.

Part III deals with the incidence and effects of the pay roll taxes. This is the longest part of the book and seems to the reviewer to exhaust the subject. The conclusion reached is that "The more or less accepted theory that labor ultimately pays the costs either through a reduction of money wages or of employment is subject to important reservations. A substantial part of the burden falls elsewhere."

While the above summaries present the author's major conclusions, they do not convey an adequate idea of the real merits of this study. These lie in the data and reasoning behind these conclusions. While mainly a theoretical discussion, a great mass of statistical and other data bearing on the problems dealt with is brought into the picture. With rare skill, the interrelation of these problems and the dependence of the correct answers upon many variables is never lost sight of.

Most of the specific questions considered are issues which were to the front before Congress amended the Social Security act in 1939. New amendments are soon to come before Congress and these raise new questions. Because the author has dealt with fundamentals, however, this study is most timely. It is certain to be widely quoted in the debate over the proposed new amendments. It is to be hoped, also, that it will influence the action taken, and, to the extent that it does so, we will have sounder social security legislation than we are otherwise likely to get.

This is a book which all those who have responsibility for formulating the social security legislation of the country should read. It is valuable also to all students of modern economic theory and of social insurance. It is an excellent illustration of the possibilities which theory affords for the sound solution of complicated economic problems.

EDWIN E. WITTE

University of Wisconsin

Society and Medical Progress. By BERNHARD J. STERN. (Princeton: Princeton Univ. Press. 1941. Pp. xvii, 264. $3.00.)

In his autobiography some years ago, the well-known economist and sociologist Franz Oppenheimer reported that his experience as a physician in Berlin at the end of the nineteenth century made him aware of the close relationship between medicine and social conditions, and led him to dedicate

his life to a socio-economic study of society through which he hoped to find an answer to the medical problem which confronted him. The author of this book has moved in the opposite direction: Research in social institutions led him to problems of physical pathology which he regards as basically social, although medical science previously had claimed them as its exclusive domain. Sharing his view, the Committee on Research in Medical Economics invited him to carry further his studies on the interrelations of medicine and society to which he had contributed in 1927 in *Social Factors in Medical Progress*. *Society and Medical Progress* is the outcome.

Medical science has never been self-sufficient. Its development, therefore, cannot be traced purely biographically, *i.e.*, by following the approach of the medical profession to its problems. Instead, it is necessary to note the close association of the growth of medicine with that of other sciences. Medicine derived special impetus, for instance, from the concept of natural philosophy; from mathematics which permitted quantitative records for description and prognosis; from biology, botany, physics, chemistry, and lately from psychology and sociology. In the last century its progress has been influenced greatly by rapid urbanization with its concomitant insanitation, congested slums, and social class stratification; by the transformation of a locally self-sufficient agricultural economy into an internationally interdependent industrial economy; by tremendous population increases; by establishment of institutions such as hospitals and public health agencies, etc. In turn, medicine has affected other sciences by revolutionary discoveries in its own field; by transforming the age composition of the population; by increasing health standards greatly; by stimulating important industries serving its ever-expanding purposes, etc.

The progress of medicine, however, has been a tragic history of prejudices, errors, obstacles, and missed opportunities. In the brilliant chapter on "Resistances to Medical Change" we become acquainted with the partly irrational, and partly calculating, forces ever in the way of medical innovation. Vested interests, personal rivalry, academic bureaucracy, intellectual blindness, doctrinarianism are the *raison* of the long and arduous, but finally triumphant, evolution of medicine from magico-religious supernaturalism to its present qualification as a science.

The progress of medicine could be much greater if socio-economic conditions were more favorable. For example, malnutrition, the cause of many diseases, is clearly an anachronism in contemporary society which has the knowledge to make an adequate food supply available to all. By showing the grievous disparity between available medical knowledge and its lagging application in social reality, the author places before society the vital alternative on which further medical development depends: either progress by transforming our socio-economic system according to medical postulates, or stagnate in the present discrepancy. It is a constructive conclusion to a thoroughly suggestive book.

PHILIPP WEINTRAUB

Cornell University

British Unemployment Programs, 1920-1938. By EVELINE M. BURNS. (Washington: Committee on Social Security, Social Science Research Council. 1941. Pp. xx, 385. $2.75.)

When in 1911 Great Britain invented the scheme of national unemployment insurance she was initiating a radical change in provision for the unemployed. Freed from the deterrent devices embodied in the age-old poor relief system, the insecure worker now by contractual right drew a specified weekly sum without the necessity of first exhausting his other resources or of submitting to the hated means test or to other coercive controls. This right was hedged about with certain economic safeguards, which limited the amount of payments and their duration in relation to a fixed number of contributions (taxes) paid by the insured or in his behalf and thus confined the system to those who were ordinarily short-period unemployed. The numbers benefited in the beginning were few and unlikely to be corrupted by generous treatment. As the magnified unemployment problem during the next three decades challenged the country to a more extended treatment, other groups of unemployed were swept into the program, category by category. Those unemployed because of the war were given from the Treasury out-of-work donations (1915-1921), and the long-time insured unemployed who had exhausted their contractual benefits received uncovenanted benefits (1921-1931), transitional payments (1931-1935) and payments from the Unemployment Assistance Board (1935 to the present), while the local poor relief (public assistance) system took full responsibility for the unemployed not comprised in these categories. In fact the local authorities were used from 1931 to 1935 as agencies to administer the means test to applicants for transitional payments from the national insurance funds. Unemployment insurance has been the basic element in this British amalgam, although in the treatment of the residual unemployed the other institutions have influenced the insurance system and have been influenced by it.

In her study of British policy in the many-sided issues concerned with large-scale unemployment from 1920 to 1938—the period between the two world wars—Dr. Burns has emphasized the interaction of insurance and of public assistance. The peculiar characteristics of insurance—limited benefits for a limited duration—required supplementary measures flexible enough to meet family needs in long-time unemployment. Once the residual unemployed also have received the right to be well treated, Dr. Burns raises the question whether unemployment insurance needs distinguishing status and whether the right to the "insurance" type of benefit has not become so firmly established in Great Britain as to make unnecessary the independent and separately financed insurance system. Progress made since 1935 in the combination of insurance and unemployment assistance—in scope, flexibility, finance and administration—suggests the possibility of a basic unification, at least in finance.

In fuller perspective Dr. Burns assesses the achievements of the British system for handling unemployment relief demands: its basic stability; its freedom from political and personal bias toward the individual; its success

in recruiting the service and coöperation of private citizens for administration; and its success in operating a complicated categorical relief program. She emphasizes the outstanding failure to initiate significant positive programs of training and public works. These successes and failures are explained in terms of their proper British social and political setting. While wisely avoiding loose comparisons of British experience with that of any other industrial country, Dr. Burns draws a conclusion which students of unemployment in all democratic countries may well ponder. Social policies and programs cannot operate in watertight compartments. "For a community which has accepted the idea of the basic minimum as fully as has Great Britain, the discovery that the sum of money necessary to assure this standard to an unemployed man may be in excess of that earned by many workers in full employment acts not solely as an argument to reduce unemployment assistance, but becomes also a challenge to remove the social inadequacies of the wage system" (p. 336).

The author's analysis of British policy as it developed step by step is penetrating, balanced, detached and realistic. It is based upon personal experience in the British Ministry of Labour, extensive interviews with officials and citizens, correspondence and documentary materials. Numerous tables in the appendix aid the American reader to appraise the extent of unemployment in Great Britain. The reviewer knows of no study of this subject which has comparable scope and analytical value.

Population; Migration; Vital Statistics

Foundations of American Population Policy. By FRANK LORIMER, ELLEN WINSTON and LOUISE KISER. (New York: Harper. 1940. Pp. xiii, 178. $2.50.)

Prepared by a committee of specialists for the National Economic and Social Planning Association, this volume will be of interest to economists primarily because it proposes a public policy. In essence, it is an appeal for the integration of population policy with national social planning. Although much has been written about European policies, this is the first book to attempt the formulation of an American plan to combat the steady decrease in the birth rate among important groups of our society.

Two generalizations are made by the authors from the demographic analysis: (1) there are certain population trends taking place in this country, especially for the middle clases, which are inherently self-destructive; (2) these trends are largely determined by social conditions and are, therefore, subject to social control. The basic objectives are set forth as a higher standard of living for the majority of our people, conservation of natural resources, and a general improvement in health and cultural capacities.

The data on which the conclusions are based consist of chapters on population trends and the relation of these trends to labor and natural resources, consumption patterns, investment and economic enterprise, social aspects, and the changing pattern of the family. It is pointed out that a decline in actual numbers seems almost inevitable. If present trends continue, the actual reproduction rate within a few decades may not be more than three-fourths, or even two-thirds, of that required for the maintenance of a permanent population. The differential birth rate places a cruel burden upon certain groups in our society to furnish the forthcoming generations. These groups, as a rule, have the fewest economic, cultural, and educational advantages. Even if this fact should not prove important from the qualitative aspect, it is doubtful that society can fully overcome these environmental factors by costly and mounting outlays. The force of the differential birth rate is brought out by some interesting facts. For example, the rate for the Spanish-Americans, Mexicans, and Indians in this country is so high that these groups may in time become as numerous as the Negro population (p. 23). In spite of the skillfully-prepared material, however, for those familiar with the previous work of Lorimer and Osborn (*Dynamics of Population*) and the recent work of Carter Goodrich and the National Resources Committee, there is little new.

The chapter on "Population, Investment, and Economic Enterprise" consists of only twelve pages and suggests that the decline in population growth may intensify the forces of depression and stagnation. References are made to articles of Professor Hansen and Mr. Keynes. In short, the remedy for this cessation of growth is planning on a national scale and the extension of governmental enterprise and services.

Of primary importance in this study are the positive measures recommended in the last chapter which may be summarized as follows:

1. Stimulation of investment and economic activity, and an increase in the general level of consumption through planning. An increased participation of the government together with an extension of public services.

2. Moderation of the present handicaps of families with several children by payments in kind by society, such as maternity care, housing programs, lunches for children, and other benefits.

3. Distribution of contraceptive information and devices equally to all classes and areas.

4. A large and wide extension of public provision for medical care, especially for mothers and children.

5. Plans, such as part-time and periodic employment and maternity leave, for the removal of the difficulties of the participation of mothers in work outside the home.

6. The development of public and community attitudes, and increased interest in children; consumer coöperatives, and other forms of community and coöperative enterprises.

All will agree that the basic objectives set forth in this book are desirable, but there will be disagreement as to how they are to be attained. The authors of course realize that population studies arouse strong emotions, and that

there will always be opposition to certain aspects of their proposed policy. Not every economist will be in agreement with the broad, national planning advocated; some are not even alarmed about the cessation of population growth.

This book says little about what seems to be the greatest gap in population literature requisite for planning—the lack of authoritative data which shows why families do not have children.[1] The availability of contraceptive measures to all classes would undoubtedly lower the birth rate, but it is not at all certain that the removal of economic burdens through public benefits, and the other measures suggested, would cause our middle-class group to have a sufficient number of chidren to replace themselves.

Myrdal, in his recent book, calls population "the grand tradition of the economist." Inasmuch as the present war will bring forth new problems, and the need for an early consideration of them, it is to be hoped that more economists will return to their "grand tradition" and join with other workers in tearing down the lettered compartments of social science and take part in formulating a policy. The book at hand is a constructive beginning.

LAWRENCE R. CHENAULT

Hunter College

Unclassified Items

Human Nature and the Social Order. By E. L. THORNDIKE. (New York: Macmillan. 1940. Pp. xx, 1019. $4.00.)

Professor Thorndike set for himself a challenging and formidable task in assembling the "substantial contribution" which "human biology and psychology" make to an "adequate science of human thought." The very attempt in its boldness calls to mind the several Outlines of H. G. Wells; but this volume lacks their readability and their intangible sense of sweep and vision and verve.

To this reviewer, Part I, which provides the background of formal psychological knowledge, is far and away the better half of the book. Here Thorndike is on ground he has made his own through a lifetime of study. One may recognize the omissions from the psychological overview—the virtual ignoring of the Freudian and *gestalt* approaches. But he has presented here what students of his texts have been taught to expect. This recapitulation consumes four hundred of the thousand pages.

Part II ranges over an enormous area of social activities, trying to establish some long-range, verifiable truths of human nature in its broad social setting. The chapter titles alone indicate a range of topics upon which it would not be surprising if any one student were less than conclusive or satisfactory in

[1] The Milbank Memorial Fund has recently completed a study on this subject.

his pronouncements. Perhaps one can most readily suggest the limitations of the method employed by a few sentences which are not too untypical.

> Common observation seems to indicate that capitalists and business men are less sharp and greedy in their dealings with their workmen than with other capitalists and business men and with the purchasing public. The purchasing and sales departments probably drive harder bargains than the personnel department . . . (p. 581).
>
> It can be argued that industrial management of the future will profit from the sacrifice of courage and dominance to reliability and coöperativeness. All these matters are more suitable for research than for discussion (p. 624).
>
> In so far as the trouble lies in our institutions, laws, and customs, science should improve them as it has improved our material instruments. If it also lies deeper, in human nature itself, science should improve human nature (p. 583).
>
> Reforms which concern the ownership of material property concern only a rather small fraction of human life (p. 698).
>
> It may further be taken as certain that the welfare of society will never be cared for by society acting by itself, but only by the acts of persons (p. 720).
>
> Psychology finds little friendship between *vox populi* and *vox dei.* It would justify majority decisions, if at all, on the grounds that they are convenient to obtain, commanded respect and allegiance in a country where they were customary, and were insurance against various pernicious sorts of oligarchy (p. 793).

If this kind of sentence is psychological science in the service of human welfare, one hopes that the science of semantics will have a prior development.

Finally, it is not captious to point out that despite the twelve-page bibliography the omissions are conspicuous as to those phases of applied psychology which have latterly had scholarly formulation. The work of the Harvard group around Elton Mayo, of Kornhauser, McMurray, Link, Houser and others, comes at once to mind.

Realization of the investment in mentality and money which this encyclopedic volume represents constitutes an embarrassment to the reviewer who would be discriminating yet appreciative. Perhaps the time has passed when any one writer should essay this kind of task. The difficulties of it for a single author are obvious. But the difficulty of the task and the eminence of the author should not deter the reviewer from announcing his conclusion that the total product is disappointing.

STEIGER, C. J. *Kalkulation und preisbildung im überseehandel.* (Zürich: Schulthess. 1941. Pp. 22. Fr. 1.50.)

Common interests and agencies of Canada and the United States. Report of Canada-United States Committee maintained by Canadian Chamber of Commerce and Chamber of Commerce of the United States. (Washington: U. S. Chamber of Commerce. 1941. Pp. 23.)

Japan trade guide, with a comprehensive mercantile directory, 1941. (S. Pasadena: P. D. & Ione Perkins. 1941. Pp. 689. $8.)

Latin America as a source of strategic and other essential materials. United States Tariff Commission, rep. 144, 2nd ser. (Washington: Supt. Docs. 1941. Pp. 397. 50c.)

World economic survey, 1939-1941. League of Nations pub. 1941. II. A. 2 (New York: Columbia Univ. Press. 1941. Pp. 260. $2.50.)

This is the ninth edition of the series and covers the period of almost two years from the autumn of 1939 to the summer of 1941. In the Preface, written by A. Loveday, director of the Economic, Financial and Transit Department of the League, the general problem of the transition from a peace to a war economy and of the sources and methods of war finance are clearly and precisely analyzed. The present volume contains new chapters on wartime control of production, consumption and rationing, international monetary relations, raw materials and foodstuffs. The report has been prepared at the Institute for Advanced Study, and ample reference is made in each chapter to American economic and financial policy.—J. C. Rocca

The world's destiny and the United States; a conference of experts in international relations. (Chicago: World Citizens Assoc. 1941. Pp. 320. Cloth, $1.; paper, 50c.)

Business Finance; Insurance; Investments; Securities Markets

DECKER, O. P. *Corporation finance.* Rev. ed. (New York: Am. Inst. of Banking. 1941. Pp. 479. $4.)

DORIS, L. and FRIEDMAN, E. J. *Corporate meetings, minutes, and resolutions.* Rev. ed. (New York: Prentice-Hall. 1941. Pp. 1163. $10.)

GREEN, P. M. and VAN ARSDELL, P. M. *Problem manual in corporation finance.* 2nd rev. ed. (Champaign, Ill.; Stipes Pub. Co. 1941. Pp. 70. $1.)

HARVEY, D. C. B. *Real estate mortgages (a practical treatise) with forms.* (New York: Clark Boardman. 1941. Pp. 346. $6.)

LANDIS, J. M. *Negotiable instruments.* Rev. ed. (New York: Am. Inst. of Banking. 1941. Pp. 400. $3.)

LEAVITT, J. A. *The voting trust; a device for corporate control.* (New York: Columbia Univ. Press. 1941. Pp. 216. $2.50.)

MACDOUGALL, E. D. *The great game of "futures"; an exposé of a gigantic racket.* (Washington: Leader Pub. Co. 1941. Pp. 108. 50c.)

MOORE, W. H. *The reorganization of railroad corporations; a study of the public interest.* (Washington: Am. Council on Pub. Affairs. 1941. Pp. vii, 173. Cloth, $3.; paper, $2.50.)

SCHLEUSS, H. *Die einbruchdiebstahl-versicherung in der Schweiz.* (Zürich: Schulthess. 1941. Pp. xvi, 270. Fr. 6.)

SHULTZ, B. E. *The securities market and how it works.* (New York: Harper. 1942. Pp. ix, 433. $5.)

STEWART, M. S. *How to buy life insurance.* Pamph. no. 62. (New York: Pub. Affairs Committee. 1941. Pp. 30. 10c.)

TAYLOR, W. B. *Financial principles and policy.* 3rd ed. (St. Louis: John S. Swift Co. 1941. Pp. 86. $2.)

WAYNE, E. A., editor. *Municipals.* Committee on municipal obligations, national association of supervisors of state banks. (Washington: Federal Deposit Insurance Corporation. 1941. Pp. 108. $1.)

WEST, C. J. *Understanding life insurance.* (Columbus: College Book Co. 1941. Pp. 308. $2.75.)

Investment counsel annual: vol. 3, no. 1. (New York: Investment Counsel Assoc. of America. 1941. Pp. 209. $1.)

Savings-bank life insurance. Labor Standards Division, bull. 44. (Washington: Supt. Docs. 1941. Pp. 22. 10c.)

Public Control of Business; Public Administration; National Defense and War

ARNOLD, T., and others. *Defense inventory.* Round table broadcast. (Chicago: Univ. of Chicago. 1941. Pp. 28. 10c.)

BASCH, A. *The new economic warfare.* (New York: Columbia Univ. Press. 1941. Pp. xvi, 190. $1.75.)

An eye-witness account of the stages leading up to the war, by a Czechoslovakian economist now teaching at Brown University. He traces the means by which Germany manipulated the trade of other countries to strengthen her own position, and explains the steps Great Britain and the United States are taking to counteract the economic *panzer* activity of Germany.

BROGAN, D. W. *Politics and law in the United States. Current problems.* (New York: Macmillan. 1941. Pp. 137. $1.25.)

An attempt to "illustrate for British readers one aspect of American institutions, the extraordinary place given to written law in the organization of American government and politics."

CLARKSON, J. D. and COCHRAN, T. C., editors. *War as a social institution; the historian's perspective.* (New York: Columbia Univ. Press. 1941. Pp. 352. $3.50.)

Most of these essays on war, by twenty-six scholars, were read at the 1940 meeting of the American Historical Association. War is discussed from five positions: the roots of war, the strategy and conduct of war, the neutral and war, war and society, and America and the present war.

———. *Defense economy of the United States, labor problems.* Foreign policy rep., vol. 17, no. 13. (New York: Foreign Policy Assoc. 1941. Pp. 11. 25c.)

DUMOND, D. L., editor. *Public policy in a world at war.* Annals, vol. 218. (Philadelphia: Am. Acad. of Pol. and Soc. Sci. 1941. Pp. 267. $2, paper.)

GARSIA, C. *Planning the war.* Foreword by Field-Marshal LORD MILNE. Penguin special. (New York: Penguin. 1941. Pp. 150. 25c.)

A study of a central war planning board with adequate executive organization. Included is a special preface to the American edition, bringing the book up to date.

HARRIS, S. E. *The economics of American defense.* (New York: Norton. 1941. Pp. 350. $3.50.)

Pp. 283. $1.)

National conference on social security. Social security in the United States, 1941. A record of the fourteenth national conference. (New York: Am. Assoc. for Social Security, Inc. 1941. Pp. 187.)

Old-age pensions: hearings, 77th Cong., 1st sess., on S. Res. 129, appointing a special committee to investigate the operation of the old-age pension system and means for securing minimum pensions thereunder; Part 1, July 14, 15, 21-24, and 28, 1941. (Washington: Special Committee to Investigate Old-Age Pension System, Senate. 1941. Pp. 234. 25c.)

Consumption; Income Distribution; Coöperation

AALTONEN, F. *Maynard weavers; the story of the United Coöperative Society of Maynard.* (Maynard, Mass.: United Co-op. Soc., 56 Main St. 1941. Pp. 72. 30c.)

ALANNE, V. S. *Fundamentals of consumer coöperation.* 7th rev. ed. (Superior, Wis.: Co-op. Pub. Assoc., Box 2000. 1941. Pp. 112. 25c.)

BENNETT, M. K. *Wheat in national diets.* Wheat stud. vol. 18, no. 2. (Stanford Univ., Cal.: Food Research Inst. 1941. Pp. 76. $1.)

HAMBLEN, S. B. and ZIMMERMAN, G. F. *Wise spending; an introduction to consumer economics.* (New York: Harper. 1941. Pp. 459. $1.80.)
A high school textbook.

MONROE, D., and others. *Family expenditures for clothing, five regions.* U. S. Dept. of Agric. misc. pub. no. 428. Consumer purchases study; farm ser. (Washington: Supt. Docs. 1941. Pp. 391. 30c.)

ROSS, J. E. *Coöperative plenty.* (St. Louis: B. Herder. 1941. Pp. 211. $2.)

TERESHTENKO, V. T. *Legal phases of coöperation.* (New York: W.P.A. for the City of New York. 1941. Pp. v, 243.)

The author presents an extensive bibliography touching upon the legal aspects of coöperation and, of even greater value to the busy reader, provides an abstract of each item. In addition, he gives the table of contents where the test of a given book or brochure deals with a number of topics. In the appendix are cited subsequent legislative actions taken on actual or proposed laws treated in the abstracts. The author has been careful to avoid the selection of only such abstracts as would suggest any specific ideology on coöperation. This volume should receive wide and practical use by those with more than a passing interest in coöperation.—Earl E. Muntz

Family expenditures for furnishings and equipment, five regions. U. S. Dept. of Agric. misc. pub. no. 436. (Washington: Supt. Docs. 1941. Pp. 212. 25c.)

Family expenditures in the United States, statistical tables and appendixes. (Washington: Nat. Resources Planning Board. 1941. Pp. 209. 50c.)

Heller committee for research in social economics. Quantity and cost budgets for four income levels; prices for San Francisco, March 1941. (Berkeley: Univ. of California Press. 1941. Pp. 108. 75c.)

———. *Quantity and cost budgets for a single working woman; prices for San Francisco, March 1941.* (Berkeley: Univ. of California Press. 1941. Pp. 10. 15c.)

Population; Migration; Vital Statistics

COLLINS, H. H., JR. *America's own refugees, our four million homeless migrants.* (Princeton: Princeton Univ. Press. 1941. Pp. 323. $3.)

MYRDAL, A. *Nation and family; the Swedish experiment in democratic family and population policy.* (New York: Harper. Pp. 456. $4.)

URLANIS, B. C. *The rise of population in Europe; essay of calculation.* (Rost naseleniya u Europe). Printed in Russian. (Moscow: State Publishing Office. 1941. Pp. 436. 8 rubles, 95 copecs.)

A detailed study of the rise of population in Europe from the earliest times to the present time and partly in the light of Marxian concepts. Contains a large bibliography in Russian and foreign languages.—P. Haensel

NOTES

Editorial Note—With this number, various minor changes are introduced into the format of the *Review*. The principal change is a completely different type which, to my eye at least, increases the ease of reading. The new design of the cover is strictly tentative and subject to later more radical changes. It had been intended to start this volume with such changes as a longer page, broader margins, and new paper and cover stock; but commitments which had been made for paper prevented it for the current year. After that, no doubt we shall be lucky to get paper at all.

The only noticeable alteration of internal structure is the running of all reviews consecutively, instead of interlarding them into the booklist. They are still kept classified, but I am inclined to the further step of ignoring the classification, and presenting them in whatever order seems good and proper. On this point I am, however, open to persuasion.—P.T.H.

The fifty-fifth annual meeting of the American Economic Association will be held late in December, 1942, at Cleveland. Russell Weisman, associate professor in the business and economics department of Western Reserve University, has been named chairman of the local arrangements committee.

The Nominating Committee of the American Economic Association has been appointed, as follows: Frederick C. Mills, National Bureau of Economic Research, chairman; William Adams Brown, Jr., Brown University; Morris A. Copeland, Division of Statistics, War Production Board; Clare E. Griffin, School of Business, University of Michigan; Donald M. Halley, The Tulane University of Louisiana; John Ise, Kansas State University; and George Terborgh, secretary, Machinery and Allied Products Institute.

The following names have recently been added to the membership of the American Economic Association:

Abelson, M., 138 Lynhaven Dr., Alexandria, Va.
Adamson, W. M., Bureau of Business Research, University of Alabama, University, Ala.
Alden, L. A., 167 East 74th St., New York City.
Alsberg, G. M., 125 Judson Court, University of Chicago, Chicago, Ill.
Arnow, P., 1913 North Rhodes St., Arlington, Va.
Ashby, L. D., Department of Economics, University of Wisconsin, Madison, Wis.
Aul, H. E., c/o Calvin Bullock, One Wall St., New York City.
Austrian, J., 1417 Eutaw Place, Baltimore, Md.
Baily, N. A., 1930 Grand Concourse, Bronx, New York City.
Ball, J. A., 940 Chrysler Building, New York City.
Barbash, J., 1415 Underwood St., N.W., Washington, D.C.
Barnes, III, W. P., 800 Drehr Ave., Baton Rouge, La.
de Beers, J. S., 2500 K St., N.W., Washington, D.C.
Behlow, Jr., R. R., Price Analysis Division, Bureau of Labor Statistics, Washington, D.C.
Bennion, E. G., 85 Prescott St., Cambridge, Mass.
Bieber, G. D., 921 Clarissa St., Pittsburgh, Pa.
Block, H., 105 Pinehurst Ave., New York City.
Boyd, R. K., Southern Junior College, Collegedale, Tenn.
Bridgeman, H. A., Connecticut College, New London, Conn.
Briley, B. B., Florida State College for Women, Tallahassee, Fla.
Brodie, H., School of Accounts and Finance, New York University, New York City.
Browne, Mrs. M. S., The Netherland House, Riverdale, N.Y.
Burchard, J. H., 3403 Lowell St., N.W., Washington, D.C.
Burnett, Mrs. E. P., Bennett Junior College, Millbrook, N.Y.
Burney, W. J., 182 Langley Road, Newton, Mass.
Cassidy, W. J., 268 North Bellefield Ave., Pittsburgh, Pa.
Cavert, W. L., 1443 Grantham St., St. Paul, Minn.
Cellarius, P., c/o Handelsvereeniging "Amsterdam," Sourabaya, Java, D.E.I.
Chang, A. C., 226 South 38th St., Philadelphia, Pa.

Clemence, R., Department of Economics and Social Sciences, Massachusetts Institute of Technology, Cambridge, Mass.
Cohen, M. A., 1925 North Humboldt Blvd., Chicago, Ill.
Comstock, E. G., 35-53 82nd St., Jackson Heights, N.Y.
Conn, H. D., 414 West 120th St., New York City.
Cook, R. C., 1731 D St., N.E., Washington, D.C.
Cunningham, S. B., 70 Fifth Ave., New York City.
Dedrick, C. L., Bureau of the Census, Washington, D.C.
Dietz, J. W., 311 East Blvd., Gainesville, Fla.
Douty, H. M., 5016 42nd St., N.W., Washington, D.C.
Dunlop, J. T., 13A Ware St., Cambridge, Mass.
Ehricke, K. N., Thomas A. Edison, Inc., Orange, N.J.
Emerson, D. W., Extension Division, Northeastern State College, Tahlequah, Okla.
Ensley, G. W., 2120 16th St., N.W., Washington, D.C.
Eulenberg, A., 110 South Dearborn St., Chicago, Ill.
Feffer, L. C., 414 George Mason Drive, Arlington, Va.
Feldstein, M. J., 1025 15th St., N.W., Washington, D.C.
Ferguson, R. H., Department of Economics, Cornell University, Ithaca, N.Y.
Fields, H. H., 1705 B St., Pullman, Wash.
Ford, A. W., Ruston, La.
Frankel, E. T., 491 State St., Albany, N.Y.
Friedman, M., Apt. 921, 2480 16th St., N.W., Washington, D.C.
Furth, J. H., Lincoln University, Pa.
Garfield, F. R., 510 Warwick Place, Somerset, Md.
Garwood, J. D., Department of Economics, Morningside College, Sioux City, Iowa.
Gilbert, Mrs. H. K., Department of Economics, University of Wisconsin, Madison, Wis.
Gillis, A., 1658 Krameria St., Denver, Colo.
Golightly, T. H., Madison-Crawford National Bank, 4010 Madison St., Chicago, Ill.
Gordon, J., 10 East 85th St., New York City.
Goss, B. C., 152 West 42nd St., New York City.
Greenberg, L., 6317 Sligo Parkway, Green Meadows, Hyattsville, Md.
Griswold, A. W., Department of Government and International Relations, Yale University, New Haven, Conn.
Grodinsky, J., 104 Hare Bldg., University of Pennsylvania, Philadelphia, Pa.
Haber, W., Department of Economics, University of Michigan, Ann Arbor, Mich.
Hall, S. M., Consolidated Edison Co., 4 Irving Place, New York City.
Harrison, D. M., Department of Economics, Ohio State University, Columbus, Ohio.
Hart, N., Apt. BB, 30 Seaman Ave., New York City.
Hawk, E. Q., Birmingham-Southern College, Birmingham, Ala.
Hayes, J. L., St. Bonaventure College, St. Bonaventure, N.Y.
Helfant, H., Casilla 9582, Santiago de Chile, Chile, S.A.
Heneman, H. G., 2130 West Como Ave., St. Paul, Minn.
Herring, J. M., 311 Logan Hall, University of Pennsylvania, Philadelphia, Pa.
Herzog, A. L., Chicago City Bank and Trust Co., 815 West 63rd St., Chicago, Ill.
Hilken, H. G., University of Kansas City, Kansas City, Mo.
Holmes, R. S., 2151 California St., N.W., Washington, D.C.
Howard, Jr., T., 2011 Columbia Road, N.W., Washington, D.C.
Jacquelin, D. G., 1701 16th St., N.W., Washington, D.C.
Jamieson, S. M., 166 Pulteney St., Geneva, N.Y.
Jensen, V. H., Department of Economics, University of Colorado, Boulder, Colo.
John, S., Dallas Power and Light Co., Dallas, Tex.
Jones, W. O., Stanford University, Calif.
Keim, A. G., 6629a Alamo Ave., Clayton, Mo.
Kendikian, A. S., 326 Audubon Ave., New York City.
Kennedy, W. F., Apt. 4-D, 530 Riverside Drive, New York City.
Killingsworth, C. C., 32 Charlcote Place, Baltimore, Md.
Kimmel, L. H., Brookings Institution, 722 Jackson Place, N.W., Washington, D.C.
Knollmeyer, L. E., 301 North Murray St., Madison, Wis.

Koch, A. R., National Bureau of Economic Research, Hillside, Riverdale, N.Y.
Labadie, J., Box 113, Aguadilla, Puerto Rico.
Landuyt, B. F., 16884 Stoepel, Detroit, Mich.
Langsner, A., 6080 North Kirkwood Ave., Chicago, Ill.
Lauter, S., 321 West 90th St., New York City.
Lemke, B. C., 114 Engineering Hall, Iowa State College, Ames, Iowa.
Lewand, F. J., 2150 Pennsylvania Ave., N.W., Washington, D.C.
Lewis, E. E., Department of Economics, Howard University, Washington, D.C.
Lewis, E. J., 628 Colfax St., Evanston, Ill.
Livernash, E. R., Tufts College, Medford, Mass.
Lonigan, E., 4714 Avenue I, Brooklyn, N.Y.
Lorenz, P. F., Hotel Southmoor, Chicago, Ill.
Lutz, W. H., 533 Orchard Ave., Yeadon, Delaware Co., Pa.
Machell, Jr., J. V., 408 North Mathews Ave., Urbana, Ill.
Mack, R. P., 430 West 116th St., New York City.
Mahoney, J. R., University of Utah, Salt Lake City, Utah.
Mallery, O. T., 9006 Crefeld St., Philadelphia, Pa.
McCoy, Sr., J., P. O. Box 559, Massillon, Ohio.
McEwen, R. J., Fordham University, New York City.
McGrew, J. G., Concord College, Athens, W.Va.
McKinley, G. W., 42 Perry Ave., Warsaw, N.Y.
McPherson, W. W., Bureau of Agricultural Economics, 249 Peachtree St., N.E., Atlanta, Ga.
Merriam, B. J., 210-A Frank Strong Hall, University of Kansas, Lawrence, Kan.
Milne, M. L., 427 Page Terrace, South Orange, N.J.
Misey, E. G., 205 Mack Hall, University of Wisconsin, Madison, Wis.
Mitchell, J. N., 26 West Sibley, Cornell University, Ithaca, N.Y.
Morey, L., University of Illinois, Urbana, Ill.
Morgner, A., Employment Stabilization Institute, University, Minneapolis, Minn.
Morrissy, E., 332 Paddington Road, Baltimore, Md.
Morse, R. L., Agriculture Annex, Iowa State College, Ames, Iowa.
Morthland, R. J., University of Connecticut, Storrs, Conn.
Murad, A., 1012 Fourth Ave., Los Angeles, Calif.
Norman, T., 3304 North 23rd St., Arlington, Va.
Norris, R. T., Vassar College, Poughkeepsie, N.Y.
Nurnberg, M., 20 Post Ave., New York City.
Ochstein, J. F., School of Business, University of Chicago, Chicago, Ill.
O'Leary, J. J., Box 58, Wesleyan University, Middletown, Conn.
Opton, I. B., 467 Central Park West, New York City.
Otte, H. F., 619 School of Business, Columbia University, New York City.
Owen, L., Carnegie Institute of Technology, Pittsburgh, Pa.
Pekelis, A., 16 Summit St., Larchmont, N.Y.
Peters, L. A. H., Netherlands Legation, 1470 Euclid St., N.W., Washington, D.C.
Pino, N., 430 West Wing St., Arlington Heights, Ill.
Potter, A. A., R.F.D. 3, Bethesda, Md.
Read, G. J., 4 Irving Place, New York City.
Rebelé, R. H., 4 Montgomery St., San Francisco, Calif.
Reinhardt, H., 779 Riverside Drive, New York City.
Riches, E. J., International Labour Office, 3480 University St., Montreal, Canada.
Rosa, J., 1916 R St., N.W., Washington, D.C.
Rosen, H. H., Brookings Institution, 722 Jackson Place, N.W., Washington, D.C.
Ruggles, R., 4 Lowell St., Cambridge, Mass.
Saletan, Mrs. A. L., 301 West 108th St., New York City.
Sarnoff, M. M., 1342 Union St., Brooklyn, N.Y.
Schenkel, A., 1322 41st St., Brooklyn, N.Y.
Schmelzle, W. K., Department of Economics, University of California, Berkeley, Calif.
Seibert, J. C., Emory University, Ga.
Seligman, B. B., 35 Crown St., Brooklyn, N.Y.

Worsley, T. B., 722 Jackson Place, N.W., Washington, D.C.
Wright, L., 4650 N. Port Washington Road, Milwaukee, Wis.
Yagoda, G., 2424 39th Place, N.W., Washington, D.C.

At the twentieth annual meeting of the Pacific Coast Economic Association, held December 29-30 at the University of Southern California, the following officers for 1942 were elected: Bernard F. Haley, Stanford University, president; James H. Gilbert, University of Oregon, vice president; Hampton K. Snell, University of Southern California, secretary-treasurer; Clark Kerr, University of Washington, editor. New members of the executive committee are Norman S. Buchanan, University of California, Berkeley; and Paul Dodd, University of California, Los Angeles. Other executive committee members are Hampton K. Snell; Elmer J. Brown, University of Arizona; and Marvell M. Stockwell, University of California, Los Angeles. Rockwell D. Hunt, University of Southern California, was elected to the Board of Trustees, of which the remaining members are Kenneth Duncan, Pomona College; and Richard B. Heflebower, State College of Washington.

The Proceedings of the meeting will be published in March or April and may be ordered from the secretary-treasurer. Single copies will cost $1.50.

The program of the 1941 conference was as follows:

The Defense Program: Labor, Prices—"Collective Bargaining and National Defense," by Evan B. Murray, Utah State Agricultural College.

Economic Developments on the Pacific Slope—"The Impact of New Land Developments upon the Agriculture of the Pacific Slope," by John A. Guthrie, State College of Washington; "The Impact of Columbia River Development upon Industry in the Pacific Northwest," by Samuel T. Moment, U. S. Department of the Interior.

The Defense Program: Finance—"Taxation as a Means of Controlling Runaway Prices," by Vernon G. Sorrell, University of New Mexico; "Fiscal Policy and the Defense Program," by A. P. L. Turner, Jr., Montana State University.

Economic Theory—"Theoretical Notes on Advertising Policy: Its Place among the Competitive Policies of the Firm," by Roy W. Jastram, Stanford University; "Uncertainty and Idle Balances," by William J. Fellner, University of California.

The Defense Program: International Economic Relations—"More Trouble for

the Latins: An Analysis of the Latin-American Trade Relations in the Present Emergency," by Clayton D. Carus, University of Southern California; "Canadian-American Economic Relations in the Present War," by A. W. Curtis, University of British Columbia.

ACCOUNTANTS' AND ECONOMISTS' CONCEPTS OF COSTS—"The Theory of Asset Valuation Implied by Accounting Principles," by Joe S. Bain, Jr., University of California; "The Use of Accounting Data in Cost Analysis," by Maurice Moonitz, University of Santa Clara.

PROBLEMS OF POST-WAR RECONSTRUCTION—"Business Confidence as a Factor in Post-War Reconstruction," by George W. Zinke, Occidental College; "Post-War Reconstruction from the Point of View of a Sociologist," by Elon H. Moore.

EXAMPLES OF ECONOMIC ANALYSIS AS A BASIS FOR PUBLIC POLICY—"The Application of Economic Analysis to American Antitrust Law Policy," by Vernon A. Mund, University of Washington; "The Proposal for Federal Incorporation or Licensing of Interstate Corporations: The Place of Economic Analysis in Evaluating the Proposal," by J. O. McClintic, Pasadena Junior College.

DINNER MEETING—"Regionalism and Economic Welfare," by Robert D. Calkins, Columbia University; "A Sociologist Looks at War," by Jesse F. Steiner, University of Washington.

The allied social science associations are being served by the following officers during the present year:

AMERICAN ECONOMIC ASSOCIATION—Edwin G. Nourse, Brookings Institution, Washington, D.C., president; James W. Bell, Northwestern University, secretary.

AMERICAN ACCOUNTING ASSOCIATION—H. F. Taggart, 1505 Delafield Place, Washington, D.C., president; Robert L. Dixon, University of Chicago, secretary.

AMERICAN ASSOCIATION FOR LABOR LEGISLATION—Joseph P. Chamberlain, 131 East 23rd Street, New York City; John B. Andrews, 131 East 23rd Street, New York City, secretary.

AMERICAN ASSOCIATION OF UNIVERSITY TEACHERS OF INSURANCE—Edison L. Bowers, Ohio State University, president; Chester A. Kline, University of Pennsylvania, secretary.

AMERICAN BUSINESS LAW ASSOCIATION—Essel R. Dillavan, University of Illinois, president; Robert E. Lee, Temple University, secretary.

AMERICAN FARM ECONOMIC ASSOCIATION—George S. Wehrwein, University of Wisconsin, president; Asher Hobson, University of Wisconsin, secretary.

AMERICAN FINANCE ASSOCIATION—Charles L. Prather, Syracuse University, president; Louis J. Long, Allegheny College, secretary.

AMERICAN MARKETING ASSOCIATION—Vergil D. Reed, Bureau of the Census, Washington, D.C., president; Albert Haring, Indiana University, secretary.

AMERICAN SOCIOLOGICAL SOCIETY—Dwight Sanderson, Cornell University, president; Conrad Taeuber, Department of Agriculture, Room 3621, South Building, Washington, D.C., secretary.

AMERICAN STATISTICAL ASSOCIATION—Alfred J. Lotka, 1 Madison Avenue, New York City, president; Richard L. Funkhouser, American University, secretary.

ECONOMETRIC SOCIETY—Wesley C. Mitchell, Columbia University, president; Alfred Cowles, III, Cowles Commission, University of Chicago, secretary.

INSTITUTE OF MATHEMATICAL STATISTICS—C. C. Craig, University of Michigan, president; E. G. Olds, Carnegie Institute of Technology, secretary.

RURAL SOCIOLOGICAL SOCIETY—C. E. Lively, University of Missouri, president; Robert A. Polson, Cornell University, secretary.

A National Study Conference on "The Churches and a Just and Durable Peace," sponsored by the Federal Council of the Churches of Christ in America was held at Ohio Wesleyan University, March 3-5. The chairman in charge of arrangements was Mr. John Foster Dulles. The conference was broken up into four study groups: (1) the political bases of a just and durable peace; (2) the economic bases; (3) the social bases,

including racial and cultural factors; (4) the church's program in relation to a just and durable peace.

Ten graduate fellowships in government management will be awarded on a competitive basis at the University of Denver under a grant from the Alfred P. Sloan Foundation. The training period may begin June, 1942, rather than September as originally announced. Applications must be filed not later than March 10, 1942. Those interested should address the Department of Government Management, University of Denver School of Commerce, Denver, Colorado.

Beginning in June, 1942, the Department of Economics of Vanderbilt University will offer a limited number of courses during the summer.

The Special Libraries Association has undertaken a complete survey of the *Special Library Resources of the United States and Canada.* Volume I recently published gives complete and detailed information on 765 libraries. The address of the association is 31 East 10th Street, New York City.

The Journal of Land and Public Utility Economics, founded by Richard T. Ely and published by him at Northwestern University since 1925, has been transferred to the University of Wisconsin.

Because so many of its subscribers were on the continent of Europe before the war, the *Review of Economic Studies* finds it necessary to replace them with American subscribers if the continuance of the publication is to be assured. Subscriptions can be paid in dollars at $2.00 a year. Checks should be sent to Paul M. Sweezy, 10 Forest Street, Cambridge, Massachusetts.

The American Academy of Political and Social Science, 3457 Walnut Street, Philadelphia, now offers student memberships at $3.00 a year instead of the regular dues of $5.00 a year. The only requirement is that the student indicate the name of the educational institution at which he is enrolled. Since student memberships were first offered in the summer of 1940, about 275 students have joined. A number of persons have given memberships to students in whom they are interested or have made gifts, leaving to the Academy the designation of the students.

The Bureau of Business and Economic Research at the University of California offers qualified graduate students an opportunity to be appointed research assistants at an annual stipend of $750. These assistantships are designed to provide personnel for the Bureau and to assist graduate students to pursue their studies in economics. Those interested should write fully about their age, academic qualifications and major lines of interest to the Bureau of Business and Economic Research, Room 204 South Hall, University of California, Berkeley, California.

Appointments and Resignations

Beatrice Aitchison resigned her position at the University of Oregon on January 1 to become an associate economic and statistical analyst for the Interstate Commerce Commission.

Dorothy Bacon, professor of economics at Smith College, is on indefinite leave of absence while working for the Office of Price Administration in Washington, D.C.

William E. Bade, formerly of the University of Wisconsin, has been reappointed a Tax Foundation-New York University Fellow for the year 1942-43.

Claude D. Baldwin has accepted a position as associate economist with the rent section of the Office of Price Administration, Washington.

Lillian P. Barnes is now an assistant economist in the Division of Research and Statistics of the Treasury Department, Washington, and is engaged in conducting research on bonds and other Treasury obligations.

Robert D. W. Bartels of the College of Economics and Business, University of Washington, has been granted leave for the winter and spring quarters of 1942 to accept an appointment in the War Production Board, Washington, D.C.

Nathan M. Becker of the University of Toledo has been granted a leave of absence

for the year to serve as economist with the Far Eastern Section of the Office of the Coördinator of Information, Washington, D.C.

David E. Bell has been appointed a teaching fellow and tutor in economics at Harvard University for the year 1941-42.

A. T. Bonnell, who spent last year in France with the Friends Relief Service, has returned to the University of North Carolina.

Roy J. Bullock has been given leave of absence by the Johns Hopkins University and has been appointed principal business analyst with the chemicals section of the Office of Price Administration in Washington.

Benjamin F. Brook, professor of economics in the College of Business Administration of Butler University, has been granted leave of absence to take a position as liaison officer with the Civil Service Commission in Washington.

Norman S. Buchanan, associate professor of economics at the University of California, has been granted a leave of absence for the spring semester to accept a position as regional price executive in the Office of Price Administration, San Francisco.

Mrs. Philip Burnett has been appointed instructor in the department of economics at Vassar College for the second semester of 1941-42.

Grant H. Calder, instructor of economics at the University of Utah for the past two years, has been appointed secretary to LeRoy E. Cowles, president of the University.

Reynold E. Carlson has been given leave of absence by the Johns Hopkins University in order to serve as economist with the Office of Price Administration, Washington.

H. Peter Carstensen, instructor in commerce at the University of Pittsburgh, has resigned to accept a position in the Navy Department at Washington.

Wayne F. Caskey, formerly an economist with the Social Security Board, has joined the staff of the Consumers' Division, Office of Price Administration, as senior economist.

B. F. Catherwood has been appointed instructor in economics at Purdue University.

H. B. Cooley, assistant professor of economics and business administration at West Virginia University, has been appointed a member of the Planning Committee of the Interstate Commission on the Potomac River Basin by Herbert R. O'Conor, governor of Maryland and chairman of the Commission. Mr. Cooley is also secretary-engineer of the West Virginia State Planning Board, having been appointed to this position in June, 1941.

Herbert J. Cummings, instructor in accounting and economics at the University of Pittsburgh, has resigned to accept a position in the State Department, Washington, D.C.

Fred M. Dannenberg, research associate at the School of Commerce, Accounts and Finance, New York University, is on leave of absence to work with the War Production Board for the duration of the war emergency.

Paul T. David, associate director and chief economist of the American Youth Commission of the American Council on Education, has devoted his time recently to drafting the Commission's general report which was published in January.

Frederick S. Deibler will become professor of economics emeritus at Northwestern University at the end of the academic year.

James L. Dohr of Columbia University School of Business has been granted a part-time leave of absence so that he may direct the research program of the American Institute of Accountants.

Nicholas Doman, formerly of the University of Chicago, has been appointed acting assistant professor of economics and government at the College of William and Mary.

Joshua Domashevitsky, formerly a teaching fellow in mathematics at the University of Michigan, has been appointed teaching fellow in economics at Harvard University for the year 1941-42.

William Duffus of Ohio State University is serving while on leave of absence as a business analyst for the Committee on Economic Warfare, Washington, D.C.

Julian S. Duncan of the Babson Institute of Business Administration has gone to

Brazil where he will be stationed at the United States Consulate-General in Sao Paulo, doing economic research for the State Department.

Kurt Ehlers, formerly on the staff of the University of the Philippines, is acting assistant professor of economics at Indiana University.

J. G. Evans has been given a leave of absence from the University of North Carolina to accept a position as economist with the War Production Board, Washington, D.C.

Homer H. Fields of the University of Illinois has been appointed acting instructor of economics at the State College of Washington.

Lyle C. Fitch has resigned from the department of accounting of the City College of New York and has accepted a position in the department of economics of Columbia College, Columbia University.

E. A. Gilmore, Jr., is on leave from the University of Nebraska to serve as senior economic analyst in the United States Embassy at Montevideo, Uruguay.

Bernard F. Haley of the department of economics, Stanford University, has been appointed chairman of the Pacific Coast Regional Committee of the Social Science Research Council.

Morrison Handsaker has been appointed acting chairman of the department of economics and sociology at Occidental College while John Parke Young, chairman, is serving in Washington, D.C.

Walter K. Handy, Jr., is now an associate fiscal analyst with the Treasury Department, Washington.

Whitney Hanks, who has held a fellowship for the past three years at the University of California, has been appointed instructor of economics at the University of Utah.

Wesley Haraldsen has accepted a position as research instructor in the Employment Stabilization Research Institute of the University of Minnesota.

Hubert F. Havlik has been given a leave of absence by Columbia University and is now working with the civilian supply section of the War Production Board, Washington.

Tyler F. Haygood, formerly of West Virginia University, is now senior taxation economist in the Tax Inquiry Division, U. S. Forest Service, Washington, D.C.

Myron Heidingsfield, formerly with Columbia University and New York University, has been appointed assistant professor of economics and business administration at the College of William and Mary. He will also continue as consultant statistician and research methodologist to the post-war planning project, Survey of Research in Recreation, being conducted by the federal government.

Herbert Heneman, Jr., has been appointed research instructor in the Employment Stabilization Research Institute at the University of Minnesota.

H. E. Hoagland of Ohio State University is devoting the majority of his time during the present year to service as chairman of the University Committee on War Activities.

John A. Hogan, formerly part-time lecturer on economics at Tufts College in 1940-41, is a teaching fellow and tutor in economics at Harvard University for the year 1941-42.

Eliot Jones of Stanford University will teach courses in public utilities and transportation in the University of New Mexico summer session in 1942.

Harold Kelso has resigned as instructor in economics at Miami University and is now an economist with the Board of Investigation and Research, Washington, D.C.

Joseph A. Kershaw has resigned as assistant professor of economics at Hofstra College to accept a position as economist with the price analysis division of the Bureau of Labor Statistics, Washington, D.C.

Harold J. King, instructor in accounting at the University of Pittsburgh, has resigned to accept a position in the Navy Department at Washington, D.C.

Melvin M. Knight, professor of economics at the University of California, is on sabbatical leave of absence for the spring semester of 1942.

John Loftus has been appointed to teach at the Johns Hopkins University for the second semester of 1941-42.

Theodore F. Marburg has been granted a leave of absence by the University of Nebraska and has accepted a position with the Post-War Division of the Bureau of Labor Statistics, Washington.

Charles F. Marsh, professor of economics and business administration at the College of William and Mary, has been granted leave of absence to serve as principal economist in charge of a study of public aids to motor vehicle transportation for the Board of Investigation and Research, Washington, D.C.

William E. Mason, formerly at Multnomah College, has joined the faculty of the College of Economics and Business of the University of Washington for the winter and spring quarters of 1942.

Gerald J. Matchett has been granted leave of absence from Indiana University to accept a research position with the Department of Commerce, Washington, D.C.

G. Roger Mayhill, instructor in history and economics at Purdue University, has been granted a leave of absence for the second semester of 1941-42.

William G. McCarroll has been appointed instructor in economics at Indiana University.

J. M. McDaniel, Jr., of the economics department of Dartmouth College, has been appointed economic consultant to the National Resources Planning Board for the New England region and will divide his time between the college and the board.

Carl McGuire, formerly an instructor at DePauw University, has joined the teaching staff of the social science department of the University of Colorado.

Raymond F. Mikesell of the University of Washington College of Economics and Business has received an appointment in the Office of Price Administration, Washington, D.C., and has been granted leave for the remainder of the academic year.

Taulman A. Miller is on leave of absence from Indiana University in order to complete a study of the effects of the experience rating provisions of the Indiana Employment Security act.

H. B. Moore is on leave from the University of Kentucky and has accepted a position as regional price economist, Bureau of Labor Statistics, in charge of the Chicago regional office which coöperates with the Office of Price Administration.

Aurelius Morgner, formerly of the University of California and more recently associated with the Wage and Hour Division in its Kansas City office, has accepted a position as research instructor at the University of Minnesota, where he is working with the Employment Stabilization Research Institute.

Eugene Myears, instructor in economics at the University of Pittsburgh, has resigned to accept a position with the Office of Price Administration, Washington, D.C.

James C. Nelson has joined the staff of the Board of Investigation and Research, established by the Transportation act of 1940, as principal economist in the section of special studies.

H. C. Nolen of Ohio State University is teaching courses in management at the University of North Carolina during the winter quarter.

Eugene E. Oakes has been granted a leave of absence from Yale University to join the staff of the Division of Tax Research of the Treasury Department, Washington, D.C.

John E. Orchard of the Columbia University School of Business is on leave for the academic year 1942-43, and is now serving as assistant administrator of the Lease-Lend Administration.

Tom Jones Parry, vice president of the West Coast Sales Co., has been appointed part-time lecturer of marketing at the University of Washington for the winter quarter of 1942.

Millard Peck has transferred from the Division of Land Economics of the Bureau of Agricultural Economics to the Economic Defense Board, Washington, D.C.

John A. Pfanner, Jr., has been granted a leave of absence by the University of Nebraska to accept a position with the Office of Price Administration, Washington.

A. F. W. Plumptre of the University of Toronto has been granted leave of absence for

the duration of the war to act as representative in Washington of the Wartime Prices and Trade Board.

Kenyon E. Poole, assistant professor of economics at Brown University, has been granted a leave of absence to accept a position in the Division of Tax Research of the Treasury Department, Washington, D.C.

Alan Post, formerly at Princeton University, is acting as a full-time instructor in economics at Occidental College during the second semester of 1942-43.

Lloyd G. Reynolds has been appointed regional price executive for Philadelphia and Baltimore, with the Office of Price Administration.

Catherine G. Ruggles has been promoted from the rank of instructor to that of assistant professor of economics at the University of Illinois.

Richard F. Ruggles has been appointed a teaching fellow in economics at Harvard University for the year 1941-42.

Caleb A. Smith has been appointed a teaching fellow in economics at Harvard University for 1941-42.

Hampton K. Snell, associate professor of transportation at the University of Southern California, has been granted a leave of absence to become senior transportation economist with the Board of Investigation and Research, Washington, D.C. He was recently elected for a third time secretary-treasurer of the Pacific Coast Economic Association.

Myron J. Spencer has been appointed a teaching fellow and tutor in economics at Harvard University for the year 1941-42.

David Kenneth Spiegel has been appointed instructor in economics and business administration at the University of Delaware.

Ernst W. Swanson, associate professor of business administration at the State College of Washington, is on leave of absence and is serving as economist in the Finance Section of the Bureau of the Budget, Washington, D.C.

Albion G. Taylor has been advanced from assistant dean to dean of the Marshall-Wythe School of Government and Citizenship at the College of William and Mary.

John V. Van Sickle assumed the chairmanship of the department of economics of Vanderbilt University at the beginning of the academic year 1941-42.

Harry Venneman has resigned his position as chief of the reference and review section, Bureau of Research and Statistics, Social Security Board, to accept an appointment as administrative analyst, Division of Administrative Management, Bureau of the Budget, Washington, D.C.

John J. Walsh has been made instructor in economics at the Catholic University of America.

Dilworth Walker, professor of economics at the University of Utah since 1928, was appointed dean of the School of Business, University of Utah, in December. He had been named acting dean following the retirement in June of Dean Thomas A. Beal.

Lauren Walker has been appointed an associate in accounting at the University of Washington.

W. Allen Wallis, on leave for the autumn quarter from the department of economics, Stanford University, is a research associate on the staff of the National Bureau of Economic Research, New York City.

Weldon Welfling of Duke University will be on leave during the second semester of 1941-42 to serve as senior economist in the coke and pig iron section of the Office of Price Administration.

W. S. Woytinsky resigned from the staff of the Committee on Social Security of the Social Science Research Council on January 1, to become principal economic consultant of the Social Security Board, attached to the Bureau of Research and Statistics, Washington, D.C.

John Parke Young, chairman of the department of economics at Occidental College, is in Washington for the duration of the war to head a group of economic advisers on

Latin American economic problems and policies who are assisting Vice President Wallace and other officials.

Erich W. Zimmermann has resigned as Kenan professor of economics at the University of North Carolina to accept the position of graduate professor of resources at the School of Business Administration, University of Texas, beginning September.

George W. Zinke, who has been an instructor in economics at Occidental College, has left to take a position as associate economist with the U. S. Tariff Commission, Washington, D.C.

HENRY CARTER ADAMS

Fourth President of the American Economic Association, 1896-97

Born in Iowa, December 31, 1851; died at Ann Arbor, Michigan, August 11, 1921. Because of delicate health he was tutored by his father rather than receiving formal schooling, until he was nineteen years of age. He then went to college; was graduated from Grinnell College in 1874. After a year at Andover Seminary, he went to Johns Hopkins University, where he studied history and economics on a fellowship, and within two years received the first Ph.D. degree conferred by that University. Thereafter he studied in Europe, and upon his return in 1879, was appointed to a lectureship in economics at Cornell University. Later he received a similar appointment at Michigan and in 1887 accepted a full-time position at that University, where he remained head of the department until his death.

Also in 1887, he was chosen statistician to the Interstate Commerce Commission, serving until 1911, and was thus led to give a large part of his energy to problems of public control, especially as regards transportation. In this field he rendered signal service, both administrative and theoretical. He served also as chief of the Transportation Division of the Eleventh Census, and spent two years in China as adviser to the government regarding railways and finance. His principal books, aside from his writings on transportation, are *Public Debts, an Essay in the Science of Finance* (1887); *The Science of Finance, an Investigation of Public Revenues and Public Expenditures* (1898); and a brief treatise on general economics called *Description of Industry* (1918). He also published many shorter studies, some of which had a wide influence, especially his memorable essay, *The State in Relation to Industrial Action*, contributed to the Publications of the American Economic Association in 1887.

A memorial to President Adams, together with an early portrait, is found in the September number of the *American Economic Review*, 1922, pages 401-16.

Henry C. Adams.

The American Economic Review

VOLUME XXXII JUNE, 1942 NUMBER TWO

WAR FINANCE AND INFLATION[1]

By WILLIAM FELLNER

The avoidance of inflation should be regarded as one of the main objectives of a reasonable war financing policy. The distribution of burdens is highly inequitable under inflation; and it becomes increasingly difficult to prevent the leaking out of scarce resources from the war sector of the economy.

The main conclusion of the present article can be expressed in a few sentences: The tax revenue contemplated in the January Budget Message should be increased significantly, if inflation is to be avoided. Price control and rationing are inadequate substitutes for anti-inflationary fiscal policies. Direct controls can be expected to forestall inflation only if the pressure against which they have to operate is held within rather narrow limits; and only in this event can we hope that the task of post-war reconstruction will not be seriously aggravated by the aftermath of *war finance*.

In the subsequent pages we shall first attempt to sketch some of the main features of American economic development since the outbreak of the war in Europe; and then we shall turn to the problem of financing the future war burden.[2]

Production and Prices—Summer of 1939 to Summer of 1941

Comparisons of "real" magnitudes for different periods are subject to well-known qualifications. While one keeps these in mind, the statement may nevertheless be risked that at the outbreak of the war in

[1] This article results from a study which is being carried on for the Bureau of Business and Economic Research, University of California. The author is indebted to Mr. Lawrence Klein and Mrs. Virginia Galbraith Tauchar for valuable research assistance.

[2] As to the recent literature on problems of American defense financing, *cf.* A. G. Hart, E. D. Allen and collaborators, *Paying for Defense* (Philadelphia, Blakiston, 1941); S. E. Harris, *The Economics of American Defense* (New York, Norton, 1941); H. W. Spiegel, *The Economics of Total War* (New York, Appleton-Century, 1942); E. Stein and J. Backman, *War Economics* (New York, Farrar and Rinehart, 1942); J. P. Wernette, "Financing the Defense Program," *Am. Econ. Rev.*, Vol. XXXI (Dec., 1941), pp. 754-66; *Financing the War* (Philadelphia, Univ. of Pennsylvania, 1942).

Europe both the real output flow of the American economy and its aggregate real capital stock were roughly at their 1929 levels.[3] Yet excess capacities (especially in the durable goods industries)[4] and unemployment of labor obviously were much higher in 1939 than in the late twenties. This made it possible to expand real output quite significantly at a price level that for one and a half years remained more or less stable.

Table I shows the percentage rise in aggregate industrial output and in certain of its constituents from the summer of 1939 to the summer of 1941.[5] As is obvious, the rate of increase was the highest in some of the typical "defense industries." No sharp distinction between defense and nondefense industries can be drawn, of course.

TABLE I—PERCENTAGE RISE IN INDUSTRIAL PRODUCTION AND IN SOME OF ITS CONSTITUENTS[a]

Classification	Aug. 1939–Aug. 1940	Aug. 1940–Aug. 1941	Aug. 1939–Aug. 1941
Industrial production, total	17.0	30.6	52.8
Manufactures, total	15.7	33.6	54.6
Aircraft	142.1	142.0	485.8
Shipbuilding	60.3	140.1	284.9
Locomotives	20.4	146.8	197.1
Iron and steel	43.6	17.1	68.2
Automobiles	26.4	31.9	66.7
Furniture	7.3	33.1	42.7
Textiles and products	1.8	38.7	41.3
Manufactured food products	3.1	16.0	19.7
Lumber	8.6	17.5	27.6

[a] Derived from data published in the *Federal Reserve Bulletin*.

Nevertheless it can be seen from production figures that the rise was not confined to defense industries in the narrower sense. Table I also reflects the circumstance that the rate of increase was much greater in the second of the two 12-month periods than in the first. Steel is a notable exception. As a consequence of the full utilization of existing production facilities and of a scrap shortage, the rate of increase in steel production slowed down in the second year of the war.

The fact that not merely defense production but also consumption

[3] As to real output, this conclusion is reached by deflating money income figures. As to real capital stock, the Kuznets estimates indicate that the capital consumption of the depression was not offset by the net capital formation of the recovery until somewhere in 1937.

[4] While in 1939 industrial production as a whole was at its 1929 level, the output of the durable goods industries was about 17 per cent lower and the output of the other industries, of course, correspondingly higher.

[5] The Federal Reserve Board's index for industrial production includes manufactures and minerals.

has risen substantially can perhaps be better seen from Table II. Department store sales, grocery chain store sales, and rural sales of general merchandise have increased significantly in the course of these two years. Here, too, the rise from the summer of 1940 to the summer of 1941 was much in excess of the rise occurring in the preceding twelve months.

TABLE II—PERCENTAGE RISE IN SALES TO CONSUMERS[a]

Outlets for Sales	Aug. 1939–Aug. 1940	Aug. 1940–Aug. 1941	Aug. 1939–Aug. 1941
Department store	10.1	36.7	50.5
Grocery chain store	11.2	24.4	38.3
Rural sales of general merchandise	11.3	42.9	59.1

[a] Derived from data published in the *Survey of Current Business.*

TABLE III—PERCENTAGE RISE IN THE COST OF LIVING AND IN SOME OF ITS CONSTITUENTS[a]

Expenditures	June 1939–June 1940	June 1940–June 1941	June 1939–June 1941
Cost of living (over-all index)	1.9	4.1	6.0
Food	5.0	7.7	13.1
Clothing	1.4	1.6	3.0
Rent	0.3	1.1	1.4

[a] Derived from data published in the *Survey of Current Business* (Bureau of Labor Statistics Index).

The figures of Table II are value figures and hence they are affected by the rise of retail prices. Comparison of Table II with Table III indicates, however, that the rise in retail sales must have been substantially greater than the increase in retail prices.[6]

The rise in the general level of both wholesale and retail prices was slight in the first of the two 12-month periods under consideration. Table IV shows the percentage increase of wholesale prices for both years and also contains data relating to the major constituents of the wholesale price index. A more detailed breakdown would, of course, show that the rise in the prices of some commodities was not negligible in the first 12-month period. Grains, dairy products, paper and pulp might be mentioned in this connection. But it is a legitimate generaliza-

[6] It should be added that the figures relating to the increase in retail sales values for the period lying between August 1940 and August 1941 are obviously affected by the new excise taxes introduced in the fall of 1941. In October, when the new tax rates had already become effective, the excess of department store sales over the same month of 1940 had declined to 11 per cent. Considering, however, that the October figures are relatively depressed by previous anticipatory buying, the October turnover must be considered high.

tion to say that the marked rise of wholesale prices over the two-year period in question is mainly a consequence of the rise in the second year. It will be seen later that the rise in the second period, in turn, was largely a consequence of the rise occurring since *March 1941.*

TABLE IV—PERCENTAGE RISE IN WHOLESALE PRICES[a]

Commodities	Aug. 1939–Aug. 1940	Aug. 1940–Aug. 1941	Aug. 1939–Aug. 1941
Wholesale prices (over-all index)	3.2	16.7	20.4
Finished products	2.4	13.0	15.7
Semi-manufactures	3.4	16.2	20.1
Raw materials	5.0	25.5	31.7
Farm products	7.5	33.2	43.3

[a] Derived from data published in the *Survey of Current Business.*

The rise in hourly earnings of labor, too, was much higher from the summer of 1940 to the summer of 1941 than in the preceding twelve-month period, although the rise of the second period is not in this case concentrated in the last few months of the period. Table V shows the percentage increase of hourly earnings for manufacturing as a whole; and also the percentage increase in nonagricultural employment as a whole. Moreover, Table V contains data as to the rise in the

TABLE V—PERCENTAGE RISE IN EMPLOYMENT, EARNINGS, AND HOURS[a]

Earnings and Hours	Aug. 1939–Aug. 1940	Aug. 1940–Aug. 1941	Aug. 1939–Aug. 1941
Average hourly earnings, manufacturing industries	5.2	11.7	17.5
Total nonagricultural employment	2.9	10.1	13.4
Aggregate labor hours performed, manufacturing industries[b]	9.1	31.8	43.7

[a] Derived from data published in the *Federal Reserve Bulletin.*
[b] *Cf.* footnote 7, below.

aggregate number of labor hours performed in manufacturing industries.[7] These latter data in conjunction with figures relating to the rise in manufacturing production (see Table I) show that a given rise in output was associated with a much smaller rise in labor hours performed in the first twelve-month period than in the second. From the summer of 1939 to the summer of 1940 manufacturing output rose by about 15 per cent and aggregate labor hours performed only by about 9 per cent. In the subsequent twelve months both indexes rose by slightly over 30 per cent.

[7] These figures are derived from the U. S. Bureau of Labor Statistics data for factory employment, on the one hand, and average hours worked per week, on the other hand.

Production and Prices: Trends after February 1941

It was stated above that the rise in the general price level was slight until early in 1941. This is true of the wholesale price level as well as the cost of living. The Bureau of Labor Statistics wholesale price index rose about 6 per cent from the outbreak of the war to January 1940, then declined about 3 per cent up to August 1940, and has risen more or less consistently since that time. But the rise from the level of August 1940 to the level of February 1941 amounted to roughly 4 per cent only, so that the entire increase for the one and a half year period lying between August 1939 and February 1941 is not more than about 7 per cent.

TABLE VI—PERCENTAGE RISE OVER THE PRECEDING MONTH IN WHOLESALE PRICES AND COST OF LIVING[a]

Classification	1941 Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	1942 Jan.	Feb.
Wholesale prices	1.1	2.1	2.0	2.6	2.0	1.7	1.7	0.7	0.1	1.2	2.6	0.7
Manufactured products	0.8	1.5	1.9	1.7	1.7	1.6	1.4	1.2	−0.1	0.9	1.9	0.6
Semi-manufactures	2.2	2.0	1.5	1.4	0.3	1.8	0.9	−0.4	−0.2	0.4	1.8	0.3
Raw materials	1.8	2.9	2.8	4.9	3.0	1.7	2.7	−0.3	0.6	2.3	4.1	0.9
Farm products	1.8	3.9	2.7	7.5	4.5	1.9	4.1	−1.1	0.7	4.5	6.4	0.5
Cost of living	0.4	1.0	0.7	1.7	0.7	0.9	1.8	1.2	0.7	0.3	1.3	0.6
Food	0.5	2.2	1.5	3.7	0.8	1.2	2.5	0.8	1.3	0.0	2.7	0.5
Clothing	1.7	0.3	0.4	0.5	1.5	2.0	3.6	1.8	0.9	0.9	0.8	2.6
Rent	0.0	0.3	0.3	0.1	0.3	0.2	0.5	0.7	0.3	0.4	0.2	0.2

[a] Derived from data published in *Survey of Current Business.*

The rise in the cost of living was negligible until March 1941. This index rose about 2 per cent at the outbreak of the war, then declined a trifle and again rose quite slightly. Early in 1941 it stood 2 per cent higher than immediately before the outbreak of the war, and one per cent higher than in the last corresponding pre-war months (*i.e.*, than early in 1939).

Since February 1941 there has been a marked upward trend in both the wholesale and retail price level. Table VI shows the rate of month to month rise for the general level of wholesale prices, for the major constituents of the wholesale price index, for the cost of living and for its constituents after February 1941.

Aggregate industrial production continued to rise at a roughly unchanging rate until June 1941, so that the period March-June 1941 is characterized by a significant rise in aggregate real output as well as in the price level. Yet after June the rise in aggregate industrial production became substantially smaller. As can be seen from Table VII, *the continued rapid expansion of some of the typical defense industries*

TABLE VII—PERCENTAGE RISE OVER THE PRECEDING MONTH IN INDUSTRIAL PRODUCTION AND IN SOME OF ITS CONSTITUENTS[a]

Type of Production	1941 Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	1942 Jan.	Feb.
Industrial production, total	2.1	−2.0	6.9	3.2	0.6	0.0	0.6	1.2	1.8	0.6	2.4	1.2
Iron and steel	2.8	−1.6	1.7	0.0	0.5	0.0	3.8	−0.5	0.0	2.6	−2.6	1.0
Aircraft	3.6	6.5	7.1	6.2	7.2	11.6	8.2	7.1	3.9	—[b]	—[b]	—[b]
Locomotives	5.9	9.7	8.0	9.4	9.6	−0.3	4.2	5.0	0.9	—[b]	—[b]	—[b]
Shipbuilding	9.1	5.4	7.9	12.3	9.1	3.9	15.5	13.2	1.7	—[b]	—[b]	—[b]
Automobile bodies, parts and assembly	−0.7	−12.7	22.6	5.9	4.3	−16.1	−5.0	9.0	−2.7	−1.7	3.3	−4.2
Lumber and products	−5.2	3.1	0.0	2.3	4.4	−0.7	−2.9	−0.7	0.0	3.6	4.3	1.4
Textiles and products	2.1	2.7	4.7	−0.6	−0.6	−0.6	−1.9	−0.7	4.0	2.6	3.9	0.6
Rubber products	1.3	1.9	2.5	18.5	−20.3	−15.0	0.8	2.3	—[b]	—[b]	—[b]	—[b]

[a] Derived from data published in the *Federal Reserve Bulletin* (seasonally adjusted).

[b] Not available for separate publication.

after June was accompanied by the cessation of growth and partly by an actual decline in other industries. This obviously is a significant phenomenon. Up to the summer of 1941 the increase in real output extended to practically all fields.

Expansionary Defense Financing

According to our estimates, the supply of money rose by about 13 billion dollars from the summer of 1939 to the summer of 1941.[8] The rate of increase was much larger in the second of the two 12-month periods than in the first. In the second period about 7.5 billion dollars of new money were created. This large increase in the supply of money from 1940 to 1941 was partly a consequence of the fact that the banks bought more than one-half of the newly issued government securities (including the fully guaranteed).[9] This in itself gave rise to about 3.5 billion dollars of new money in the fiscal year ending in June 1941. Furthermore, the banks had expanded their loans to private business by the important amount of 3 billion dollars;[10] and the gold inflow was

[8] We have included demand deposits adjusted; deposits of the U. S. Treasury and of foreign banks in the Federal Reserve banks; and currency outside the Treasury and the banks. The foregoing two types of deposits in the Federal Reserve banks are not usually included in the concept of money, but there is no reason for excluding them since they are drawn upon to make current expenditures.

[9] For the period June 1940 to June 1941, the percentage of new issues going to banks was 51.5 per cent; to insurance companies, 7.3 per cent; to "other investors," 20.4 per cent; to federal agencies and trust funds, 20.5 per cent.

Banks include Federal Reserve banks, member banks, other commercial banks, and mutual savings banks. The holdings of the Federal Reserve banks changed but slightly.

[10] Loans of all banks (millions of dollars): June 30, 1939—$21,318; June 29, 1940—$22,341; June 30, 1941—$25,312. Source: *Federal Reserve Bulletin.*

also associated with the creation of new money. The flow of money spending increased in approximately the same proportion as that in which the stock of money rose. The exchange velocity index of the Federal Reserve Bank of New York declined from 1939 to 1940, and since then has risen slightly, but not beyond its pre-war level. Income velocity seems to have declined slightly from 1939 to 1941, but this decline is so small that, considering the limitations to which the estimates are subject, it seems preferable to say that income velocity has remained approximately constant.[11] The conclusion then would be that money spending has risen in the same proportion as that in which the supply of money has increased. This proportion is roughly one-third if the summer of 1941 is compared with the summer of 1939, and the proportion will not be very different for the calendar year 1941 as compared with the calendar year 1939.

The bulk of the rise in supply of money and in the flow of money spending has occurred in the second, rather than in the first of the two 12-month periods. This second period roughly coincides with the first year of the American defense program. The "defense program," in the technical sense, was started after ten months of war in Europe, during which some amount of monetary and real expansion had already occurred in this country. The fiscal year ending June 1940 which precedes "the first year of the defense program" must really be regarded as the first year of war expansion. The assumption that the war was the prime mover of the American expansion in the course of the fiscal year 1940 can be made plausible with reference to the development of exports,[12] and this assumption becomes even more plausible if account is taken of the fact that the rise in industrial output was at that time already largely concentrated in the typical defense industries.[13] Yet American defense spending was but slightly higher in the fiscal year ending June 1940 than in the fiscal year ending June 1939;[14] and the difference in the government deficit of the two fiscal years was negligible.[15] Consequently, the fiscal year ending June 1941 may be con-

[11] Income velocity for the year 1939 was 1.97; for 1940, 1.88; and for 1941, 1.89. The method used was to divide income payments by the stock of money. All income figures are estimates of the Department of Commerce. Velocity figures based on income produced, rather than income payments, would be almost precisely the same.

[12] For fiscal year ending June 1941, total exports were $3,838,927; exports to Europe were $1,620,482. For the fiscal year ending June 1939, total exports were $2,919,732; exports to Europe were $1,228,429. Total exports were 31.1 per cent higher in fiscal 1940 than in fiscal 1939. Exports to Europe were 32.0 per cent higher. Source: *Survey of Current Business.*

[13] See Table I.

[14] 1.7 billion dollars as against 1.2 billions.

[15] The excess expenditure of the federal government was 3.5 billion dollars in fiscal 1939 and 3.6 billions in fiscal 1940. If this deficit is corrected in the manner to be described later in the text, the figures are 2.1 billions for 1939 and 2.4 billions for 1940.

sidered the first year of the American defense program not merely in the formalistic sense but also in the sense that the specific problems of defense financing first arose in this fiscal year.

The methods of financing the defense program were distinctly expansionary from the outset.[16] The rise in tax revenues and the decline in expenditures other than those on defense[17] was insufficient to provide the funds necessary to finance the rapidly rising defense outlays. Moreover, the gap was too large to be closed by borrowing from the public at that time. These circumstances reflect themselves in the increased government deficit of the fiscal year 1941 and in the fact that the government relied heavily on borrowing from the banks. From the fiscal year 1940 to the fiscal year 1941, the national defense expenditures of the federal government rose from 1.7 billion dollars to 6.1 billions and this was associated with a rise of the crude deficit from *3.6 billions* to *5.1 billions*. These deficit figures should, however, be corrected so as to take account of the receipts and expenditures of the government agencies technically not included in the concept of the federal government. If this correction is undertaken the net figure of *4.7 billion dollars* is obtained for fiscal 1941, *which is almost precisely double the corresponding figure for the previous fiscal year.* This figure expresses the excess expenditure of an aggregate consisting of the "government" plus its agencies.[18] The government, in the foregoing broader sense, has obtained almost two-thirds of its aggregate borrowings from banks.[19]

Inflation Potentialities before and after December 7, 1941

The danger of inflation was imminent in the last stage prior to American belligerency. It was obvious before the attack on Pearl Harbor that the defense program would lead to inflationary phenomena at an increasing rate unless monetary and fiscal policies were changed. Defense spending for the present fiscal year was then estimated at 18 to 19 billion dollars and aggregate federal spending at 24-25 billion dol-

[16] By "expansionary" we mean "leading to an increase in MV." The term is used in this sense by Hart and Allen, *op. cit.*

[17] Mainly unemployment relief.

[18] The "government" plus its agencies, taken as one unit, borrowed 5.4 billion dollars in the course of the fiscal year 1941, the difference between this latter figure and the aggregate excess expenditure (4.7 billions) being explained by the fact that the General Fund Balance of the "government" and of the agencies rose by .7 billion.

[19] As was pointed out in footnote 9 on p. 240, the banks bought 51 per cent of all newly issued government securities (including the fully guaranteed). But they bought almost two-thirds of those newly issued securities which were not bought by federal agencies. If we regard the federal government and its agencies as one unit, then this latter figure expresses the share of the banks.

lars, while tax revenues promised to yield around 12 billions.[20] Consequently, the crude deficit of the federal government was expected to reach 12 to 13 billion dollars. Moreover, the outlays of the government agencies, mainly those of the R.F.C. and of its subsidiaries, were rising rapidly. These agencies play an important part in the financing of defense investment. It was obvious that the corrected deficit of the government in the broader sense would reach in the present fiscal year a multiple of the 4.7 billions of fiscal 1941. Three times this figure did not seem a high estimate at that time. It is true that voluntary lending was also on the increase and, consequently, it was not clear whether borrowing from the banks would have risen very substantially. In the first six months of the present fiscal year, over 4 billion dollars of Defense Savings Bonds and Tax Anticipation Notes have been sold to the public. With these two types of borrowing at an annual rate of 8 to 10 billion dollars, borrowing from the banks would not necessarily have amounted to much more than in fiscal 1941. In spite of this it was clear that the inflation danger had increased. Up to the summer of 1941 practically all industries had expanded. Since that time the rise in defense production was associated with a decline in civilian output. Hence, up to the summer of 1941, the increased flow of purchasing power was directed at an increased flow of real civilian output; since that time, the rising flow of purchasing power has been directed at a shrinking flow of civilian commodities. Consequently, the same increase in the flow of money spending would inevitably have been associated with an increased inflationary pressure. It was safe to conclude already in November 1941 that the danger of inflation would rise, unless tax revenues were increased beyond the then contemplated level.[21]

The inflation danger was aggravated by a further circumstance. The stock of idle deposits obviously rose by a substantial amount during the first two years of the war. This follows from the fact that neither exchange velocity nor income velocity had risen, while the stock of money grew by a little over one-third. Since a significant change in the velocity of the *active* part of the stock of money is unlikely to have occurred, it must be concluded that the new money was divided into active money and idle money in approximately the same proportion as that in which the 1939 stock had consisted of these two constituents.[22] Or, to express the same thing in other words: both the active part and the idle part of the stock of money must have risen by approximately one-

[20] On the grounds of the new tax bill, passed in the fall of 1941.

[21] Bank *loans* might also have increased somewhat more than in the preceding fiscal year. Yet on the other hand the gold inflow has slowed down substantially.

[22] It seems quite likely that the velocity of the active part of the money stock has increased slightly. In this event idle balances must have risen slightly more than proportionately.

third if a rise of the entire money stock by one-third was unaccompanied by a change in the average velocity of the dollar. We know that the stock of idle money was already substantial in 1939. The income velocity of the dollar, for example, was about one-third lower at the outbreak of the war in Europe than in the late twenties.[23] This reflects the high level of idle balances at the time of the outbreak of the war in Europe. The failure of velocity figures to rise during the monetary expansion since 1939 indicates a further substantial rise in the stock of hoards. A general desire to get rid of idle balances would have a significant inflationary effect. It might be pointed out that a rise of the income velocity of the present stock of money to the velocity level of the 1920's would increase the yearly rate of money income by roughly 60 billion dollars.

It is obvious that the gravity of the problem increased significantly after war was declared. This is true even with respect to the present fiscal year. Defense spending for the current fiscal year is now estimated at roughly 28 billion dollars (instead of 18 billions) and aggregate federal expenditures at about 34 billions (instead of 24 billions). Tax revenues for the present fiscal year will apparently not exceed the previously estimated 12 billions and, consequently, the estimated deficit has risen by about 10 billion dollars (to almost 22 billions). This means a higher rate of monetary expansion and also a higher rate of output-curtailment in the civilian sector.

For fiscal 1943 the war expenditures of the federal government and its agencies are estimated at 70 billion dollars and aggregate federal spending at 70 to 75 billions. If the revenue of the federal government (including the planned increase in Social Security contributions) will be raised merely to about 27 billions, as is now contemplated, an enormous rise of the monetary pressure seems inevitable. A large portion of the roughly 45 billion dollars of borrowing would undoubtedly have to be of an inflationary character.

The Ideal Degree of Taxation

It is suggested in these pages that the rate of taxation be increased substantially beyond the now contemplated level.

The notion that rationing and price control might be used *instead* of appropriate fiscal policies is an unfortunate one for several reasons. First, it should be pointed out that, with the monetary pressure rising rapidly, the enforcement of rationing and price control would require a very substantial and costly effort on the part of the authorities. In

[23] See James W. Angell, *Investment and Business Cycles* (New York, McGraw-Hill, 1941). See mainly, chap. 9, and Appendix II.

fact, if the pressure grows significantly, it is unlikely that the effort would be successful. Second, there is general agreement in democracies as to the desirability of keeping policing activities down to that minimum which is indispensable for wartime efficiency. This implies that it is preferable to reach a given objective by methods which do not require policing rather than by methods which do. Narrowing the flow of money income is superior in this respect to price control and rationing. Third, it should be emphasized that it is undesirable to create conditions which automatically give rise to a cumulative upward movement of prices as soon as measures of control are relaxed. In order to realize this, it is important to draw a line between the immediate post-war "short run" and the subsequent period. In certain stages of post-war readjustment it will be necessary to maintain the flow of money income by measures of public policy. Expansionary effects will then be welcome. But in the immediate post-war short run, there presumably will be a strong tendency for re-stocking. Even if it should prove to be true that very severe regimentation enforced by efficient policing agencies could prevent an inflationary spiral for the time being, a failure to keep money income down would strongly accentuate the inflationary phenomena of the post-war short run and would unnecessarily deepen the subsequent depression.

As we shall see later, this does not mean that price control and rationing should be omitted. We merely believe that *measures directed at the aggregate income stream should provide the basic structure of a reasonable anti-inflation policy.*

By measures directed at the aggregate income stream, we mean taxation and borrowing from the public. Neither of these two measures can be directed exclusively at the current income stream, since the public may reduce its hoards or increase its borrowings from the banks when buying government securities or when paying taxes. This is a qualification which must be kept in mind and to which we shall return presently. The necessity of combining taxation with price control and rationing is largely a consequence of this potentiality. For the moment, however, we may view taxation as well as borrowing from the public as measures directed mainly at the current income stream. We may also regard compulsory loans as a form of taxation which will be refunded. Let us therefore at first distinguish taxation and compulsory loans, on the one hand, from voluntary loans subscribed to by the public, on the other; and let us view these two types of war finance as being directed mainly at the current income stream.

At the present income level,[24] it would presumably be possible to

[24] By the "present yearly rate of income," we mean a rate of about 100 to 110 billion dollars. The present level of taxation means the level obtaining in fiscal 1942.

finance a *moderately heavy* war burden largely by voluntary loans. But it will be argued that the share of voluntary lending in the non-inflationary financing of a *very heavy* war burden would have to become small. The point here is not merely that a very heavy burden is greater than a moderately heavy burden. More important is the fact that heavy taxation is bound to reduce those funds which otherwise would be lent to the government.

At the present income level it would be unreasonable to expect more than 15 to 20 billion dollars of net voluntary savings; or, if some degree of capital consumption is imposed upon the economy, more than 20 to 25 billions of gross savings.[25] More could be expected only on the assumption that the government enforces all-around price control and rationing against an increasing monetary pressure and thereby successfully imposes upon the public a higher rate of saving. A policy aimed at avoiding the monetary pressure in question should, of course, not be based on this assumption. Now, at the present level of income and of taxation 35 billion dollars (12 billions revenue at present rates and the rest voluntary lending "out of current gross income") would be quite insufficient to provide the funds required for the armament program. This would be 30 to 35 per cent of national income instead of the required 60 per cent.[26] If, however, the tax revenue must be increased substantially, then the amount to be raised by voluntary loans out of savings is bound to shrink. The degree of taxation necessary to bridge most of the gap corresponding to 25 to 30 per cent of national income would eliminate individual saving.[27]

The emphasis of a consistent anti-inflation program should be placed on taxation. An efficient tax policy should be supplemented by security sales, but once the degree of taxation becomes sufficient we cannot expect voluntary lending to amount to a high share of aggregate expenditure. Or rather voluntary lending could in these circumstances be substantial only if it is undertaken by means of depleting idle cash balances, in which event it fails of its purpose as a method of non-inflationary financing.

The taxation program should take account of two main points of view. The distribution of burdens is one of these and the specific character of the commodity shortages the other. The first point of view calls clearly for income taxation since income taxes can be made progressive.

[25] Various estimates lead to the conclusion that the annual depreciation of the present stock of durable producers' goods and buildings slightly exceeds 10 billion dollars.

[26] Under the most recent scheme, total expenditures of the Treasury would correspond to about 60 per cent of the national income.

[27] Moreover, in the absence of direct consumers' controls, the saving ratio would tend to decline even at present tax rates, since consumers' real income, in the here relevant sense, will be made to decline.

The second point of view calls for supplementing income taxation by excise taxes on specific commodities. The specific commodity shortages will undoubtedly be created by direct government allocation, that is, essentially by commandeering. As it becomes necessary to shift more resources from civilian production into the armament industries, the government will continue to allocate the resources in question to the enterprises producing for defense. The shortage in a great number of civilian commodities will be and already is a direct consequence of these measures falling in the category of commandeering. But a reasonable taxation program should take account of the specific character of these shortages since otherwise the demand would exceed the supply of certain commodities at all prices except tremendously high ones. In other words, at practically all levels of income taxation there will be a high upward pressure on the prices of certain highly scarce commodities. It is probable that these prices will rise, even though the government does attempt to keep them down by direct control and policing. For durable commodities of high scarcity, the second-hand markets will become the really important ones, and it is very unlikely that prices on these markets could be kept at present levels by direct control. It would be desirable to utilize this rise in prices for the purposes of the armament program by the means of excise taxes and thereby to tax away amounts which otherwise would go into windfall profits. Price fixing will be more effective if it occurs at higher levels, at which the excess of demand over supply is smaller. It is impossible to estimate with any degree of accuracy the yield of excise taxes on the assumption that additional excise taxation is applied only to tax away otherwise inevitable price increments in fields of high scarcity. At the present level of taxation the aggregate yield of excise taxes may be estimated at somewhat less than 3 billion dollars[28] and the assumption would seem reasonable that this yield could be approximately doubled at the present income level. It would, of course, be possible to raise the yield of excise taxes much beyond this level in case taxes were imposed upon necessities for which the demand is notoriously inelastic. But from the social point of view, this is no desirable method of financing a war burden. Excise taxation requires specific justification owing to its nonprogressive character. It can be justified with respect to luxuries and more or less "harmful" commodities, and it can be justified in those cases dis-

[28] The "present level" does not yet include the new proposals of the Treasury submitted in March 1942. The yield of excises in the fiscal year 1941 amounted to 2.4 billion dollars. In the October 1941 issue of the *Survey of Current Business,* the yield of the additional excise taxes which became effective October 1, 1941, is estimated at about .5 billion. For an entire year the addition would, of course, be higher than for the period October 1-June 30. Yet the substantial curtailment of the consumption of numerous taxed items will be a factor tending to reduce yields. The proposals submitted in March 1942 are expected to increase the total yield by 1.3 billion dollars.

cussed above where the tax may be expected to have mainly the effect of utilizing for the Treasury an inevitable rise of prices. The excise taxes imposed on highly scarce commodities would, of course, not yield much if merely newly produced commodities were taxed. Extension of excise taxation to used markets might raise the yield, but it is obvious that if high excise taxes are applied only in the cases discussed here, but a small share of the aggregate war expenditures could be raised from this source.

It follows from these considerations that the bulk of the burden should be raised by income taxation. It is obvious from the outset that personal income taxes can be made to yield much more than corporate income taxes and it will be seen presently that it would not be advisable to increase even the *rate* of corporate income taxation to the level of personal income taxation. In case the significance of voluntary lending "out of current income" is substantially reduced—and this is bound to happen if taxation becomes very heavy—it would be desirable to raise an amount corresponding to about 35 per cent of the national income by personal income taxation.

We have no means of calculating precisely the burden falling upon the single income brackets. The following might, however, be a rough way of obtaining an idea of the general orders of magnitude involved in such taxation. The National Resources Committee has estimated the distribution of income for the period July 1935 through June 1936; and also gave estimates, based on specific assumptions, of income distribution for higher levels of aggregate income.[29] To raise 35 per cent of personal incomes, on the basis of the distribution there estimated for an 80-billion dollar income level,[30] would require roughly the following. Assuming that families *of average size* with incomes of less than $1,000 should be exempt and that the rate at which $1,500 incomes are taxed should not exceed 15 per cent, the effective rate would have to amount, for consumer units with the average number of dependents, to about 30 per cent on incomes of around $3,000, to about 40 per cent on incomes of around $4,000, to about 50 per cent on incomes around $6,000, to about 60 per cent on incomes around $10,000. The *average* rate of taxation on incomes of more than $20,000 would have to come close to 90 per cent.[31] By saying that these would have to be the effective rates,

[29] *Consumer Incomes in the United States,* National Resources Committee, 1938. *Cf.* also *Consumer Expenditures in the United States,* N.R.C., 1939, secs. 3-5.

[30] We are using those estimates which imply for 80 billion dollars the same proportionate distribution as has existed for 60 billions.

[31] Using the National Resources Committee's estimates for an 80-billion dollar income level, it is easy to convince oneself of the fact that a scale of the above character would raise about 35 per cent of the Committee's "total." (*Cf. Consumer Expenditures,* 1939, p. 190, under heading "same proportionate distribution as in 1935-36.") To reproduce the calculation would require more space than is at our disposal.

we mean that the tax rates would have to be such as to make the actual tax payments correspond to the percentages indicated above. The exemption of low incomes would obviously require that the nonexempt portions of incomes be taxed at correspondingly higher rates.

There is a presumption on the one hand, that a tax structure, yielding about 35 per cent of an 80-billion dollar income on the basis of the National Resources Committee's estimates, would yield a *higher portion* of a 100- to 110-billion dollar income (probably close to 40 per cent).[32] This is true because the recent increase in national income was undoubtedly associated with a rise in the average income level so that at present a larger share of aggregate income is earned by relatively higher income groups. Understatements of income and evasions of various kinds make it necessary, on the other hand, to undertake a rather substantial *downward correction.* In fact, the National Resources Committee used, among other sources, the income tax returns in estimating the income flowing to the higher brackets and has raised the resulting share of these brackets quite substantially for nonreporting and understatement. Aside from the question of evasions, it should be remembered that certain constituents of aggregate income are not subject to individual income taxation. The war burden, when related to income, is usually expressed in percentages of national income produced. Some constitutents of income produced (such as, for example, corporate savings and non-cash income) do not enter into the individual income tax base. Hart and Allen have estimated[33] that, at a 90-billion dollar income level, these reducing factors[34] might curtail the income base by roughly 15 per cent of total income. Moreover, increased corporate taxation and, conceivably, the limitation of dividend payments would somewhat diminish the share of the higher brackets in aggregate individual income payments. It might, therefore, be assumed that a tax structure of roughly the character sketched above would be capable of yielding close to 35 per cent of the increased national income.[35]

[32] A scale yielding 35 per cent of 80 billion dollars would yield 40 per cent of 104 billions on the assumption that about 60 per cent of the rise goes to the Treasury. The scale of the text would probably tax away around 60 per cent of the increase.

[33] *Cf. op. cit.*, p. 147.

[34] Reducing factors other than personal exemptions; and other than the earned income credit, which presumably will be dropped.

[35] This is another way of saying that, *from the point of view of this percentage figure,* the upward correction for increased income might, roughly speaking, cancel out with the downward corrections for evasions and nontaxables. On the assumption of footnote 32, above, the downward correction would outweigh the upward correction from the point of view of the percentage figure if the Hart-Allen estimate regarding nontaxables and evasions is correct and if the average nontaxable and concealed income belongs in a bracket for which the marginal rate of our scale is about 70 per cent. On these assumptions, which seem reasonable, the 35 per cent would decline to 30 per cent. Yet if, in the future, money income would be rising at the rate of increase of real output, this percentage figure

The ultimate (long-run) distribution of burdens could be made even more progressive by applying some version of the Keynes plan to the lower income brackets. The use in this connection of the administrative structure of the Social Security system has repeatedly been suggested.

Considering what has been said above about excise taxes, it is likely that this kind of taxation could be made to yield roughly 5 per cent of total income without exceeding the limits appearing as "justified" on previously discussed criteria. Furthermore, corporate income taxes plus borrowing from current corporate earnings could probably be made to contribute 10 to 12 per cent of national income;[36] and such borrowing as is offset by capital consumption in the civilian sector of the economy, to contribute an amount corresponding to another 5 per cent. Hence the aggregate revenue of the Treasury plus borrowing out of current gross income could reach a level corresponding to about 55 per cent of income.[37] Taking account of the fact that war spending and the other expenditures of the Treasury will require 60 per cent, a residual amounting to about 5 per cent of income would have to be borrowed from banks.[38] Hence, the supply of money would be rising at an

---

would also be rising somewhat. A comparison of figures derived by the crude method sketched in the text with Treasury estimates as to the yield of specific tax scales would seem to indicate that the method does provide some information regarding rough orders of magnitude.

[36] Corporate profits, net of intercorporate dividends, amounted to roughly 10 to 11 per cent of national income in the recent past. (See Hart-Allen, *op. cit.*, chap. 12) There is a strong presumption that they correspond to a higher proportion at present. Assuming this proportion to be 14 to 15 per cent and assuming legislation which would limit dividend payments, a fund amounting to 10 to 12 per cent might become available for taxation plus borrowing. If, say, the average effective tax rate would be raised to 60 per cent of the corporate earnings, these taxes would yield about 9 per cent national income and borrowing conceivably about 3 per cent.

For the fiscal year 1942 the yield of corporate income taxes, including the excess profits tax, may be estimated at roughly 4 billion dollars. This figure is derived from 1941 yields, on the one hand, and estimates relating to the additional yield of recently increased tax rates, on the other. (See *Survey of Current Business,* October, 1941.)

[37] Items of revenue, other than mentioned above, are of negligible order of magnitude.

[38] It would be important to eliminate excess reserves by raising reserve requirements. At present the government is forced to rely heavily on borrowing from the banks and it could rely *to a small extent* on this type of borrowing even if a scheme were adopted which would successfully avoid "inflationary phenomena." Yet, on purely rational grounds, it would seem preferable to sell government securities to the *Federal Reserve banks,* rather than to commercial banks. The latter procedure, as opposed to the former, presupposes the existence of excess reserves and, hence, leaves a door open for *further* monetary expansion *via* an increase in loans to private business and to individuals. It should not be overlooked, however, that the spending of funds borrowed from the Federal Reserve banks leads to the formation of further excess reserves, unless reserve requirements are continuously adjusted (or so changed as to take care of this in advance). Furthermore, irrational factors should also not be overlooked. Direct borrowing from the Federal Reserve banks would open a very easy channel for inflationary borrowing; and it is conceivable that the incentive to raise funds by taxation, rather than borrowing, would thereby be weakened.

annual rate of about 10 per cent.[39] This would produce no "inflationary pressure." Aggregate real output must also be expected to rise slowly.[40]

In connection with corporate income taxes we should like to point to the following. If corporate income taxes are compared with personal income taxes, then, for obvious reasons, it is found that relatively lower corporate income tax rates for the various income brackets will yield a relatively higher portion of aggregate corporate income. This is a consequence of the more top-heavy distribution of corporate incomes. Corporate income taxes, including the excess profits tax, should of course be made to yield a considerably higher share of aggregate corporate income, than the 35 per cent suggested for personal incomes. Yet it would hardly be reasonable to raise corporate income tax rates for the various corporate income brackets to a level as high as that which would have to apply to personal incomes of the same magnitude. The risk that production becomes inefficient if industrial efficiency remains entirely unrewarded is substantially greater than the risk that individuals withhold their services on account of being taxed too heavily. Moreover, the resistance against taxing away practically all corporate incomes would be even greater than resistance to extraordinarily heavy individual taxation. An attempt to break this resistance fully would not be worth while, since the difference between the yield of the present corporate income tax structure and that of a confiscatory tax would not amount to more than about 7 to 8 per cent of national income. Last but not least, it should be realized that corporate surpluses can be made into a more reliable source of lending than personal incomes. In fact, corporate savings would become the only source of voluntary lending "out of net income," since no individual savings could be expected under such a scheme. Hence, while it is desirable to raise corporate income tax rates beyond their 1941 level, it would not be reasonable to raise them to the levels suggested for personal incomes of identical size. Instead, dividend payments could be limited; and the investment of corporate surpluses in government securities could be stimulated by making tax rates dependent upon how the undistributed surpluses are used.

It should be stressed that, while increased reliance on excise taxes, rather than on income taxes, would diminish progressiveness, financing

[39] Income velocity is in the rough order of 2. Consequently, 5 per cent of income corresponds to roughly 10 per cent of the stock of money.

[40] Yet it should be borne in mind that the potential rise in *industrial* production definitely overstates the potential rise in *aggregate* real output. As to the slow rise of industrial production in recent months, see Table VII above. It should not be expected that in the future course of the war the average annual rate of increase in aggregate real output will exceed 5 per cent by any substantial margin.

by excise taxes is much less undesirable than inflationary financing on the scale now contemplated. Excises and sales taxation share lack of progressiveness with inflation. But excise taxes and sales taxes in themselves do not tend to disorganize the currency and thereby to reduce economic efficiency. Furthermore, certain commodities could be exempted from sales taxation, while they could not be exempted from a cumulative price rise. We do not mean to deny that, in so far as rationing and price control are completely effective, *controlled* inflation may, for the duration of the war, distribute the consumption burden more equitably than do sales taxes. Yet direct controls, such as rationing and price control, are unlikely to prevent a considerable rise in the price level if the monetary pressure becomes very high and the postwar difficulties also increase substantially in case the temporarily sterilized purchasing power of the war period becomes excessive. *The substitution of increased excise taxes or of a general sales tax for some portion of the income taxes suggested above would be distinctly less harmful than inflationary borrowing on the now contemplated scale.*

A severe taxing policy would have to be combined with certain measures of price control and rationing.[41] This is true mainly because no degree of taxation would reliably prevent the wealthier groups of the population from maintaining their consumption by depleting their idle balances. This is another way of saying that taxes may be paid out of previously accumulated hoards and that loans, too, may be made from these sources rather than "out of current income." The curtailment of consumption for which we are heading is obviously very significant. All calculations point to the necessity of cutting per capita real consumption to deepest depression levels. Considering the absence of unemployment in war periods and also the growth of population during the last decade, this may imply standards considerably lower than those of 1932 for the middle and upper brackets. The resistance against such a substantial reduction of the standard of living will be strong. If free competition among consumers were maintained and taxes were raised to the level considered above, dishoarding would undoubtedly become a means of partly maintaining consumption standards. This is the main reason why income taxation in itself does not necessarily result in an equitable distribution of burdens[42] and also does not, in itself, prevent

[41] We mean here price control and rationing of consumers' goods. The allocation of resources to armament industries, considered above, obviously implies rationing of resources.

[42] The other reason is that, in fields of especially high scarcity, prices will tend to rise at practically all levels of income taxation. It was suggested above that this problem be handled by the means of excise taxes. It is desirable to combine excise taxation with price control and rationing rather than to rely entirely on excise taxes. As was pointed out in the text, the justification of excise taxes in these cases is that direct controls alone would presumably not prevent a rise in prices effectively. By means of excises, the inevitable rise could be utilized for the purposes of the Treasury.

the leaking out of scarce resources from the war sector of the economy into the civilian sector. Price control and rationing are insufficient substitutes for a reasonable taxation policy; but price control and the rationing of scarce essentials are necessary to supplement an equitable and efficient policy of war finance.

It should be added that the deduction of income taxes at the source, wherever the "source" is distinct from the income recipient, would greatly facilitate the achievement of these objectives. This method would have the advantage of substantially reducing the time lag between legislating and collecting. Many persons would thereby be induced to adjust their budgets to changed taxes simultaneously. Deduction at the source may also reduce administrative expenses, although certain administrative difficulties should not be overlooked. The main difficulty would seem to be that of handling the problem of residuals which cannot be settled before the tax year is over. The *final* yearly tax of an individual cannot be calculated before his yearly income is known, since under a progressive income tax the yearly income is one of the determinants of the rate which should have been applied.

Conclusion

The "ideal" tax policy discussed in the foregoing pages would enable the Treasury to refrain from inflationary borrowing. In reality we must take it for granted that some portion of the war fund will be raised by inflationary methods, although a serious effort will no doubt be made to sterilize the additional money stock in the hands of the consumer by the means of direct controls. But if these controls are to be reasonably effective and if the problem of post-war readjustment is not to be aggravated considerably, the ideal degree of taxation should be approximated much more closely than is now planned.

According to the Budget Message submitted to Congress on January 7, 1942, the aggregate revenue of the fiscal year ending June 1943, would amount to about 26 or 27 billion dollars.[43] This figure includes about 2 billion dollars expected from increased Social Security contributions. The detailed tax proposals of the Treasury were submitted to Congress early in March. Total expenditures of the Treasury for fiscal 1943 will exceed 70 billion dollars and consequently the deficit reach a level of about 45 billion dollars. Taking account of the increased tax burden but disregarding for a moment price control and rationing, it may be assumed that not more than about 20 billion dollars of the total borrowing would tend to come out of current gross savings. The rest would tend to become inflationary borrowing. The

[43] Individual income taxes would apparently yield about 8 billion dollars and corporate income taxes, including the excess profits tax, about 9 to 10 billions.

supply of money now being in the order of 50 billion dollars, there would be a tendency for inflation at an annual rate of about 50 per cent.[44] Price control and rationing would have to obviate this tendency and thereby to enforce a higher rate of saving. But it does not seem possible to work against a pressure of this magnitude successfully. Taxation should be increased substantially beyond the now contemplated level before it is too late.

University of California

[44] The tendency may even be in excess of this, considering that the supply of consumers' goods will be declining simultaneously.

THE FUTURE OF FROZEN FOREIGN FUNDS

By JUDD POLK

Over 7 billion dollars in foreign-owned assets are now subject to regulation by the United States Treasury Department. (See Table on p. 266.) The presence of extensive exchange controls in a country long distinguished as the foremost champion of free exchange raises questions of the most far-reaching significance for the future course of international finance. It will be the concern of this paper to examine the circumstances under which the American controls operate with a view to determining what conditions may be necessary or desirable before the United States can safely reopen its money markets to foreigners.

The immediate objective of any exchange control is to bring foreign transactions under the scrutiny of a governmental agency in order that the particular purposes of the government may be enforced. While these purposes differ widely among the various countries,[1] they ordinarily are concerned with (1) the rationing of foreign exchange rendered scarce by continued strains, arising from the balance of payments, on cash resources,[2] and/or (2) the supervision of imports with a view to influencing the terms of trade or in support of internal economic policies of the government. In general it may be said that government intervention in the foreign exchange markets has been provoked in most cases either as a necessary feature of governmental regulation of trade, or as a sort of temporary receivership for deranged national accounts, where the alternatives—uncontrolled currency depreciations or formal devaluations—were thought to be more onerous methods of securing the needed correction in the balance of payments.

I. The United States Version of Exchange Control

The United States had two grounds for opposing the world-wide trend toward exchange control, which in the years 1931-39 put every important exchange market save our own on a controlled basis.[3] The

[1] Professor Ellis distinguishes functionally seven types of exchange control, ranging from the prevention of capital export to the bolstering of totalitarian economic and political control. (H. S. Ellis, "Exchange Control in Germany," *Quart. Jour. of Econ.*, Aug., 1940, 159-68.) United States' wartime controls are comparable with the latter class, with the important distinction that they are *wartime* (*i.e.*, temporary) controls.

[2] Rationing exchange by some means other than currency depreciation is here meant.

[3] The British and French markets were not strictly controlled until the war made it necessary. However, the development of British bilateralism was sufficiently rapid throughout the thirties to prevent the classification of sterling as strictly free. See H. J. Tasca, *World Trading Systems* (Paris, 1939), pp. 141-57. The French market was subject to frequent—though perhaps not sufficiently frequent—rate revisions. See P. Einzig, *World Finance, 1939-1940* (New York, 1940).

first was a matter of economic faith—that increased governmental interference with international finance would impose an incubus on international trade.[4] The many facets of this faith are hard to define, but perhaps the Hull program may be considered an application of it in modern circumstances. It does not insist that exchange markets shall be absolutely free of all government regulation. Rather it contemplates that, though regulation may be undertaken in the interests of protecting international currency relations against speculative derangement and "downward spirals" initiated by depression, such regulation shall none the less be confined within limits consistent with the conception of exchange markets as mechanisms facilitating the adjustment of the international balance of payments.[5]

Whether this faith suited the circumstances of other countries or not, it was clearly more appropriate to our own international economic position than acceptance of the trend toward exchange controls would have been, and this was the United States second ground for opposing the exchange control. Throughout the difficult thirties the United States never experienced any really awkward shortage of exchange. A chronically active balance of trade (4 billion dollars, 1935-40), coupled with a torrential flow of both long- and short-term capital to this country (7.4 billion dollars, 1935-40),[6] produced not an exchange shortage but an *embarras des richesses*. The manifestation of these circumstances was the unprecedented 12 billion-dollar influx of gold in these years.[7] But even in the event of an exchange shortage, our relatively small ratio of foreign to domestic trade would have kept the problem less than crucial in our national economic policy. As it was, we were more concerned with the fact that our credit balance in commercial and capital transactions with the rest of the world was frozen by the controls adopted by countries in circumstances precisely the reverse of our own.

[4] However, W. Diebold (*New Directions in Our Trade Policy*, New York, 1941, chap. 2) finds that available evidence on the effect of the Hull anti-control program on trade does not support the proposition that a removal of controls stimulates imports. But this may have been merely the failure of the import-stimulating aspect of the policy to overcome the effects of the devaluation of the dollar as a stimulus to exports. *Cf.* Imre de Vegh, "Imports and Income in the United States and Canada," *Rev. of Econ. Stat.*, Aug., 1941, p. 137. De Vegh found that during the period of pronounced increase in exchange controls, the League of Nations figures show a drop in the marginal import ratio (*i.e.*, the slope of the regression of world imports on world industrial production) from .95 in the period 1925-29 to .49 in the period 1932-38. (*Ibid.*, pp. 138-39.) Ellis also believes that exchange controls reduce the volume of trade and discusses the evidence. (*Op. cit.*, pp. 184-91.)

[5] *Cf.* Tasca, *op. cit.*, pp. 158-60; J. Donaldson, *The Dollar* (New York, 1937), pp. 193 *ff*.

[6] This figure was derived from *Federal Reserve Bulletin* figures on capital movements and earmarked gold. The dates are inclusive.

[7] *Ibid.*

Despite the opposition of the United States to the trend,[8] foreign exchange markets outside of this country had become alarmingly "unfree" by the summer of 1939. The imminence of war gave added impetus to the world-wide flight to the dollar. Repatriation of American foreign investments (804 million dollars, 1935-40),[9] the United States Treasury's gold purchases,[10] the transfer of foreign-owned funds to the uncontrolled American market in the interest of liquidity and security —all these factors in the general movement were intensified by the threat of war, and later by the war itself. This one-way movement of international funds, which foreign controls originally encouraged, came to be in itself a major cause for the continuation and extension of such controls, and developed into the main problem of international finance in the pre-war period. No solution was in sight when the war itself, bringing rigid new controls in its wake, indefinitely postponed the search. Before the war brought us a completely different order of financial concerns, the main problem for the United States was how to foster international financial institutions which would dispense with the competing, arbitrary, and discriminatory controls imposed by various nations for various purposes, without merely returning to the magnificent disorder which originally prompted those controls. It is to this problem that the United States will have to return after the war.

However, when the United States returns to the problems of peace finance, it will do so not as the world's leading advocate of "free finance," but as the world's most powerful practitioner of exchange control. The present controls were adopted in response to a dilemma occasioned by Germany's military seizures. In April, 1940, when the first controls were imposed, there was no problem of capital flight or exchange shortage to be met. The United States had simply to choose between sacrificing its free exchange policy and allowing Germany, less reluctant in controls, to take over the American holdings of invaded countries. It chose the former.

[8] To a large extent the opposition of the United States was merely verbal. We did not liberalize our trade policy significantly. The Hull program apparently favored exports more than imports. (Diebold, *op. cit.*, pp. 9, 22.) The devaluation of the dollar and the high tariff policy played some part in driving other nations to adopt exchange controls. *Cf.* M. A. Gordon, *Barriers to World Trade* (New York, 1941), p. 30. On the other hand, the United States did continue to buy gold despite the proportions of its flow here, and that was a definite step supporting a "free finance" policy, whether that was the actual motive of our gold purchases or not.

[9] *Federal Reserve Bulletin* figures on international capital movements.

[10] The bulk of the gold sales were, of course, merely the means of effectuating the flow of capital to the United States. None the less, for new gold the United States was the only practical buyer in the world. Similarly, large amounts of gold ordinarily held in reserve abroad were shipped here. Accordingly, it is proper to include transfers of gold to this country as an independent manifestation of the "flight to the dollar," and the existence of a steady gold market here as one of the reasons for that flight.

By subjecting to Treasury licensing all transactions involving a property interest of any national of an occupied country, the United States hoped to accomplish several objectives.[11] Most immediately, the Treasury's scrutiny of such transactions was intended to be a protection to owners in invaded countries. In addition, however, it was designed to afford some measure of protection to the American custodians—mostly banks—of the property of these owners.[12] In lieu of government intervention, the custodians had no legal basis for refusing to honor legitimate drafts; and they had no factual basis on which to determine whether a given draft was drawn under German duress or not. A further, though much more remote, prompting of the American controls was the thought that American creditors and investors might eventually be benefited by the government's efforts to keep the assets of invaded countries intact.

For these purposes it was thought sufficient to require licenses only for those transactions which involved the property of the invaded nations. However, experience with enforcement readily showed, and policy belatedly recognized, that effective prevention of any specified class of transactions meant rigorous supervision of *all* transactions involving a foreign interest.[13] Moreover, as the United States increasingly undertook economic measures against the Axis, a new motive for exchange control appeared: the bolstering of our anti-Axis economic policy by means of a financial blockade. Hence, from a limited control intended primarily to protect invaded countries, the United States exchange control grew in a year to a thoroughgoing Treasury supervision of any foreign financial transaction which might redound to the benefit of the Axis.

[11] The motives of the freezing are available in the press accounts of interviews with government officials. See, for example, "Treasury Studies Legality of Policy of Foreign Assets," *Jour. of Comm.*, July 19, 1940, and editorial in the *New York Herald Tribune,* April 12, 1940. See also Treasury Department Appropriation Bill for 1942, Hearings before the Subcommittee of the House Committee on Appropriations, February, 1941, 77th Cong., 1st sess., pp. 78, 82-83, 84, 85; *Banking,* Aug., 1941, pp. 24-25; A. M. Strong, "The Freezing of Foreign Assets," *Am. Banker,* July 22, 1941. Later motives of economic warfare were specified in the official Press Release accompanying the Executive Order freezing Japanese and Chinese assets, July 26, 1941. J. W. Pehle, Assistant to the Secretary of the Treasury, in charge of the Division of Foreign Funds Controls, reviewed the purposes of the control and its development in a luncheon address before the Foreign Credit Interchange Bureau in March, 1941 (mimeographed). For an inferential summary of purposes, see "Foreign Funds Control through Presidential Freezing Orders," *Columbia Law Rev.*, June, 1941, pp. 1042-44.

[12] However, the issuance of a license does not necessarily determine the licensee's right to the funds involved, except in the case of foreign public funds where the State Department has been authorized by statute to certify the right of the claimant. Pub. Doc. No. 31, 77th Cong., 1st sess., chap. 43, S. Doc. 390.

[13] " 'Freezing' of Assets May Be Broadened," *Jour. of Comm.*, February 11, 1941; "Millions in U. S. Money Withdrawn by Italians," *New York Herald Tribune,* May 3, 1941; "Reich Liquidating Its Credits Here," *New York Times,* April 17, 1941; and editorial in *The* (London) *Economist,* Feb. 1, 1941.

In form the control is simply a supervisory power over financial transactions with foreigners,[14] delegated by the President under statutory authority[15] to the Secretary of the Treasury. Under the President's orders[16] any transaction with, or for, or in behalf of, a foreign national of 35 specified countries[17] requires a Treasury license. To obtain such a license the parties to a proposed transaction must submit to the Federal Reserve Banks notarized forms setting forth all relevant details.[18] The banks forward these applications[19] to the Treasury's Division of Foreign Funds Control, where the facts are examined in the light of policies determined by an Inter-Departmental Committee. A licensee must keep a record of the transaction and may be required to report.[20] In addition, all holders of foreign property are required to report the nature of the holding to the Treasury.[21] Failure to conform to the orders is punishable by 10 years' imprisonment, or $10,000 fine, or both.[22]

The immediate problems of the control are those which concern its wartime effectiveness in preventing economic benefits to the Axis and economic detriments to victims of the Axis.[23] These problems are largely short-run problems of administration and, as such, do not raise sig-

[14] A fuller description of the control can be found in Hearings on the Treasury Department Appropriation Bill, *op. cit.*, pp. 76-105; Amos E. Taylor, "Frozen Funds and National Defense," *For. Comm. Weekly*, Aug. 9, 1941, pp. 6-7; "Property Census—An Element in Foreign Funds Control," *ibid.*, Aug. 16, 1941, p. 6.

[15] The President's authority derives from the Trading with the Enemy act of October 6, 1917, sec. 5 (b) (40 *Stat.* 415), as amended by the Emergency Banking act of 1933 (48 *Stat.* 1), and the Joint Resolution of May 7, 1940, which last see for the final version of the power. Pub. Res. No. 69, 76th Cong.

[16] The "freezing orders" issued under this authority date from April 10, 1940 (Executive Order No. 8389, amending Order No. 6560 of January 15, 1934) to December 26, 1941 (Executive Order No. 8998, amending earlier orders so as to extend freezing automatically to all territory occupied by the enemy). The basic control documents, namely the Executive Orders, General Rulings, General Licenses, Public Circulars, Proclaimed List of Certain Blocked Nationals, and the Presidential Proclamation authorizing the list, are all available from the Treasury or the Federal Reserve Banks.

nificant issues in international finance.[24] The problem of what is to be done after the war, however, raises really vital questions of financial policy. And the consideration of these questions cannot be postponed until the return of peace.

The absence of government exchange controls has been habitually described—it may be wondered why—as a state of "free exchange." Any country's regard for free institutions may well command respect in these times, but a willingness to justify chronic disorder by labeling it "free" is merely an invitation to authoritarian controls. From this point of view, the striking characteristic of international finance from 1919 to 1939 is not that it was converted from a free to a controlled basis in most nations, but that, whether controlled or free, it moved in a more or less unbroken crescendo of disorder, punctuated at the beginning and end of the period by the complete rupture which world war entails.[25] Thus after the war the question will scarcely be one of deciding whether or not to return to pre-war financial institutions. There is literally nothing to return to. The question will be how to induce some degree of order in a field carrying a long tradition of disorder.

II. An Approach to Policy

In the remaining paragraphs of this paper it will be argued that: (1) The circumstances attending the return of peace will not be auspicious for an unqualified removal of United States controls, because such a removal would likely result in an arbitary allocation of United States goods not on the basis of international needs but on the basis of accrued claims, and because the unrestrained expenditure of such claims would embarrass the rebuilding of an adequate mechanism for international finance. (2) The possibilities in an international clearance of claims are not promising, either as a means of disposing of frozen claims here and abroad, or as a step in the reconstruction of international finance. (3) Only a comprehensive and carefully planned pattern of economic reconstruction will make possible a satisfactory handling of the frozen funds. In such a pattern of reconstruction, the frozen funds could, with considerable freedom, play a useful rôle.

Unqualified removal of controls. At the close of the last war, the wartime controls, which were very similar to the present ones, were

[24] The problem of securing Latin American coöperation in the control may be thought of as an exception to these statements. The international control techniques now (February, 1942) being worked out in the hemisphere will unquestionably have some influence on the development of post-war finance.

[25] For brief accounts, see P. Einzig, *op. cit.*, chap. 3; M. A. Gordon, *op. cit.*, pp. 7-46; J. B. Condliffe, *The Reconstruction of World Trade* (New York, 1940), chaps. 2, 3.

removed almost immediately.[26] It might be supposed in the first instance that a similar procedure would be appropriate after this war. After all, are not the frozen claims legitimate obligations of the United States? Short of a desire or willingness to repudiate these debts, what basis would the United States have for refusing to release the funds for whatever use their owners should elect to make of them?

This line of thought, however, oversimplifies the complications which may embarrass the free use of foreign funds after the war. Obviously the mere fact of a debt's existence is not a sufficient reason to support the unqualified freedom of international funds. The very existence of wartime restrictions shows that circumstances may arise under which obligations other than those of a simple debt nature may be regarded as determining the status of foreign funds. The question then is whether the circumstances of the immediate post-war period may, like the war itself, point toward the maintenance of some restrictions on the use of foreign claims.

The first objection to an unqualified release of the funds is that such a step would inevitably lead to an arbitrary international allocation of the available American goods. That such goods will be in intense demand after the war seems clear, in view of the industrial demoralization of war areas. If the goods are to be allocated through ordinary market processes, the owners of the frozen funds would gain an arbitrary advantage. How arbitrary is clear when it is recalled that the frozen claims have no necessary relation to a given nation's war sacrifices or post-war needs. For example, France presumably will have intact most of its current frozen holdings; China, Britain and Russia will have no substantial holdings at all (except their current gold production). Conceivably the problem of these arbitrary purchasing-power disparities might be approached in terms of new loans or post-war lease-lend arrangements. Since, however, the effectiveness of foreign purchasing power is limited by the export potentialities of our economy,[27] any leveling of arbitrary advantages via increasing the funds available to foreigners would force the United States (1) to permit an inflation of export prices, with the attendant depreciation of the dollar at the expense of domestic consumers, or (2) to adopt export controls, in which

[26] A presidential order of July 26, 1919, freed foreign accounts except for certain restrictions on Central European exchange, which were retained to facilitate the work of the American Relief Administration, and restrictions on transfers to Bolshevik sections of Russia, which were retained as part of the general United States policy vis-à-vis Russia. By December, 1920, even these restrictions were removed. Federal Reserve Board, *Annual Report,* 1919, pp. 48-49; *ibid.,* 1920, p. 34.

[27] These potentialities will probably be relatively low in the immediate post-war period when our economy is still geared to the production of war goods.

case we are in effect controlling foreign exchange.

In a period of post-war unemployment there might be considerable pressure on the government to adopt just such a policy of stimulating exports in order to increase domestic employment. The merits of this suggestion cannot conveniently be explored here, but we may note three strong objections: (1) the conscious inflation of export prices is itself a form of debt repudiation, a result utterly inconsistent with the motives here assumed to base its adoption; (2) it is doubtful that it would lead to any desired allocation of United States goods; and (3) as far as the (good) effect on employment in the United States is concerned, similar stimulation could be obtained by domestic-market projects, without any loss of product via exports.

The second objection to an unqualified release of the claims is that their complete liquidation might be a considerable blow to the reconstruction of international finance. As is well known, the 7.5 billion dollars in frozen claims[28] were originally acquired directly or indirectly through the shipment of gold, securities, and merchandise for sale in the United States. The movement of long- and short-term capital in the years 1935-40 itself built up a large part of these claims: 3.2 billion dollars in bank balances, 1.25 billions in earmarked gold, 803 millions in foreign securities, and 101 millions in brokerage balances.[29] The very fact that such funds could be transferred from other countries to the United States illustrates that some sort of system of international finance was *operating*, whether well or badly. Instruments of international monetary significance (*e.g.*, gold and securities) did exist. In effect the capital movement meant that balances which were formerly maintained in various markets came to be shifted to the United States market. The gold which the United States acquired in consequence remains available to secure their convertibility. For all practical purposes the United States became the international bank of the world, with substantially all international funds maintained here, and substantially

[28] Estimated as of the end of 1941. D. W. Bell, Under Secretary of the Treasury, listed the holdings of Denmark, Norway, The Netherlands, Belgium, Luxembourg, France, Latvia, Estonia, Lithuania and Rumania at 4.4 billion dollars based on a Treasury census of frozen holdings. (Hearings, *op. cit.*, p. 80.) My estimate for other countries is based on Federal Reserve and Commerce Department figures, corrected for estimated capital movements and checked against estimates made informally by various interested government agencies. For the country-by-country breakdown, see the Table, p. 266. It is to be borne in mind that, for the purposes of the freezing orders, many holdings which would not ordinarily be defined as "foreign" are included. (See footnote 17, *supra.*) Such inclusion might make the figure some 25 per cent larger than estimates of foreign holdings made for other purposes. To serve as an estimate of frozen funds at the end of the war, the figure would have to be qualified further by reductions or increases through licensed transactions during the war. The volume of these transactions is not available, but scattered evidence in the press on licensing policy and the *Federal Reserve Bulletin's* figures on current capital movements to and from certain of the frozen countries suggest that the frozen funds are being kept substantially intact.

[29] Derived from statistics on international capital movements in the *Federal Reserve Bulletin.*

all the international reserves (gold) here too.[30] No one can question the technical soundness of the reserve position of the United States. International claims could be completely liquidated in gold without disturbing the larger portion of these reserves. In the light of this unprecedentedly strong reserve position, why would the system of international finance be endangered by removing restrictions on foreign funds?

The danger is paradoxical only on first glance. United States gold reserves are not inadequate in the usual sense. They are merely irrelevant. There are good reasons to believe that a lifting of restrictions would not start a movement from dollar claims to gold, but rather from gold to dollars, just as before the war. These reasons are, firstly, that the post-war needs of nations owning dollar resources or gold are such as to urge their expenditure on goods; and, secondly, it seems unlikely that they will be in a position to remove their own controls after the war.[31] The United States, alone being capable of selling goods and amenable to buying gold, will become the place where international claims are cashed—not in gold, but in goods. The position of the United States is roughly comparable to that of a bank whose depositors all want to cash their deposits, but refuse to accept cash. This upside-down result is only another facet of the financial inversion which, as other writers have noted, has put gold on a dollar standard.

If this sort of encashment of international claims should be allowed to take place, as well it might, it would amount superficially to an honoring of international claims, but in reality to a winding-up of the system of finance to which they are relevant. The United States in effect would have "cashed" all the world's gold in a procedure through which the gold loses any further international monetary significance. The gold standard would paradoxically be lost through the very steps taken to save it. This paradox, though, is only another reminder that an international standard, gold or other, depends on international policy, not on unilateral action by a single nation.

Thus we may conclude that an unqualified removal of restrictions on foreign funds would be undesirable because (1) it would amount to an arbitrary allocation of limited United States production among the needy nations in the post-war reconstruction, and (2) it would tend to dissolve the available mechanism of international finance by permitting

[30] An accurate estimate of funds capable of conversion into dollars but not now in this country is not really possible. Of some interest is the Federal Reserve estimate that at the end of 1939 the potential dollar purchasing power of foreigners, including gold reserves not actually in this country, was 17.4 billion dollars. *Federal Reserve Bulletin*, Dec., 1939, p. 1042. This estimate does not, of course, take into account lease-lend balances or other war credits.

[31] The problem of maintaining a balance of payments without further depreciation of war-weakened currencies, and of expending the available foreign exchange resources on the imports thought to be most necessary in a reconstruction period, may be expected to prompt a continuation of controls, unless the nations can be persuaded by an offer of alternative advantages to relax their controls. This possibility is treated below in the text.

the complete liquidation of instruments formerly possessing international significance.

Before turning from the desirability of removing our exchange controls without any further understanding as to the use to which the freed funds can be put, two other aspects of the problem should be mentioned, though they cannot be discussed in any detail here. The first is to note that the legal consequence of removing the controls would be to turn over to the courts the innumerable complex problems of ownership and public policy which are bound to arise. The courts, in determining which of several foreign claims to various funds should be honored, would have no well-developed definition of public policy on which to rely.[32] The problem would be especially formidable in the event that the United Nations should fail to bring about the restoration of France, Belgium, and The Netherlands, the largest owners of frozen funds. (Together, these three countries own over half of the frozen funds.) The second is the political importance of the defeat of Germany. If Germany is not defeated, the likelihood that the United States would permit Europe's American funds to be used, under German direction, for the purchase of American goods seems most remote, quite apart from the economic considerations discussed above.

An international clearance of debts. The United States might well feel that the disposition of foreign claims in this country does not represent a problem suitable for unilateral action by this country, but rather represents one aspect of the larger problem: What is to be the post-war fate of international claims everywhere? Recognizing this larger problem, some observers, including Secretary of the Treasury Morgenthau, felt, even in the early weeks of our control, that the frozen foreign funds might afford a means of securing for American investors and creditors at least a partial payment on their outstanding claims against foreigners.[33] This concern about foreign debts was not new. Discussions of the defaulted European war debts, the defaulted South American loans, the German-blocked dividends and interest payments, and the Mexican expropriations provide much evidence of its place in American foreign policy.[34] But the United States had never before been in a position to undertake directly retaliatory action; there were no foreign balances in this country to be blocked abroad. The war-prompted flight

[32] For a discussion of the state of the law relevant to the settlement of foreign claims, see *Columbia Law Rev., op. cit.*, pp. 1048 *ff.*, and an extended note on "Protective Expropriatory Decrees of Governments in Exile—Their Application to the United States," in the same issue, p. 1072. See also Arthur Nussbaum, *Money in the Law* (Chicago, 1939), chap. 8.

[33] See, for example, "U. S. May Use Funds of France on Debt," *New York Times,* Aug. 9, 1940; *PM,* Oct. 10, 1940.

[34] See J. W. Gantenbein, *Financial Questions in United States Foreign Policy* (New York, 1939), chap. 1 and *passim.*

to the dollar changed this situation by radically changing our balance of payments.[35] The influx of foreign capital resulted in the piling up of European balances here, despite our favorable balance on current account. At the end of May, 1941, for instance, the *Federal Reserve Bulletin* reported foreign banking funds in this country at 3.9 billion dollars, in contrast to a mere 364 millions reported by United States banks as their foreign holdings. So the United States had the power, if it wished to exercise it, to do what England had frequently done during the past decade—insist that, before foreign balances would be released, some agreement should be made designating a portion of the funds to be used in satisfaction of foreign debts.

The figures for total foreign investments of Americans abroad and of foreigners here appear to suggest that such a payments agreement might provide for extensive compensation to American investors and creditors. Our assets abroad at the end of 1940 were estimated by the Department of Commerce to be slightly over 11 billion dollars, or 23 billion dollars if obligations arising out of World War I are included. If only the countries whose American assets have been frozen by the President's orders are counted, our foreign investments are as follows:[36]

Direct investments	$1,051	million
Portfolio investments (dollar bonds)	613	"
Short-term ("Banking") funds	80	"
World War I debts	8,069	"
	$9,813	"

The frozen assets, we have seen, are estimated at 7.5 billion dollars.

However, the possibilities of offsetting American claims against frozen foreign claims is less promising than these totals might suggest. If the clearance is undertaken on a country-by-country basis,[37] a lump

[35] After 1935 the United States might have blocked foreign balances to force a settlement of debts to Americans, but strong political considerations operated increasingly against the step. We hesitated to demoralize further the already demoralized European markets, and we were still hopeful that our efforts in behalf of free finance would be successful. *Cf.* Secretary Morgenthau's defense of the government's gold-buying policy. Letter to Senator Wagner (Mar. 22, 1939), Treasury Department, Press Release, March 23, 1939.

[36] See table, p. 266, and footnote 28 for sources.

[37] If the occupied countries owning frozen assets here are restored after the war, clearance on a country-by-country basis would be the only possible method. A lumping together of European funds would, of course, be to some extent an appropriation of the assets of one country to pay the debts of another. If the European countries are not restored, or if Germany remains in control of Europe, then there would be somewhat more justification for treating the assets as "European." In this event, however, the procedure would be less a reciprocal clearance than a unilateral action by the United States, recognizing the loss of its European investments, and appropriating European assets here as an offset.

figure of foreign investments is not an appropriate indicator of clearance possibilities. From the table below it can be computed that the frozen assets of eight countries exceed our placements there, also frozen,

A PARTIAL BALANCE SHEET OF AMERICAN AND FOREIGN CLAIMS[a]
(In millions of dollars)

Country	Foreign claims against United States	United States claims against foreigners		
		World War I	Other	Total
Austria	$ 9	$ 26	$ 6	$ 32
Belgium	760	401	53	454
China	275	0	140	140
Czechoslovakia	5	165	7	172
Denmark	92	0	111	111
Finland	17	8	10	18
France	1,593	3,864	167	4,031
Germany	107	1,225	382	1,607
Greece	122	32	24	56
Hungary	24	2	33	35
Italy	72	2,005	155	2,156
Japan	131	0	197	197
Latvia, Lithuania, Estonia	29	29	53	82
Luxembourg	48	0	—	—
Netherlands	1,619	0	96	96
Norway	175	0	91	91
Poland	7	206	81	287
Portugal	157	0	17	17
Rumania, Bulgaria	55	64	56	120
Spain	30	0	86	86

Switzerland	1,484	0	12	12
U.S.S.R.	39	192	10	202
Yugoslavia	71	62	33	95
Total	$7,437	$8,281	$1,844	$10,125

[a] Not listed here are Thai assets, frozen on December 9, 1941. Furthermore an amending order of December 26, 1941 froze Hong Kong and provided for the automatic freezing of all further territories occupied by the enemy. Executive Order No. 8988.

Sources: For foreign holdings in the United States, see footnote 28. The United States claims arising from World War I are taken from the United States Treasury's *Annual Report*, 1940. Other United States investments are estimated by correcting the Commerce Department's figures for 1936 (the last year for which the figures are available by country) on the basis of the increase shown in Commerce Department's estimates for our investments in all countries in 1939 (United States Department of Commerce, Release of July 15, 1940). Figures for our investments in Luxembourg are not available.

by 4.3 billion dollars, indicating that this amount of the frozen funds would not be available for offsetting purposes.

If a further distinction is drawn between government and private debts, and private assets are excluded from clearance against public debts, a further reduction must be made in the amount of frozen foreign

funds which might be disposed of by clearance. The amount of reduction on this score can be estimated only roughly, since available statistics do not distinguish between private and public funds. But there is reason to believe that, by-and-large, the frozen funds are about two-thirds private, and one-third government and central bank.[38] If this estimate is correct, clearance would take care of only 1.5 billion dollars.

In addition, certain reductions must be made in the American claims which might appropriately be allowed. The clearing estimates given above have lumped all American claims together—war debts, private claims, dollar bonds. It is at least doubtful, however, whether the United States should or would insist that the old war debts be included in clearance. An obvious element of inequity would arise from the circumstance that the major debtors of World War I are, with the exception of France, the countries with small American holdings. Of the 8 billion dollars in war debts owed by the countries with frozen American holdings, three-fourths are owed by three countries: Germany (1.25 billion dollars), Italy (2 billion dollars), and France (3.9 billion dollars). England, with an old war debt of 4.4 billion dollars, would escape the clearance altogether. Moreover, the United States might decide as a matter of policy that a portion at least of the public funds of The Netherlands, Belgium, Poland, Czechoslovakia, Greece and Yugoslavia should be turned over to Britain in accordance with understandings, already reached or to be reached by the end of the war, between Britain and the governments-in-exile of these countries. If for these or other reasons it should be felt inappropriate to include the old war debts in the clearance, then the only American claims against the public funds of the frozen countries would be 500 million dollars in dollar bonds.[39] A clearance of 347 million dollars is the greatest possible on this basis.

In making these clearance calculations, private claims have been excluded on the grounds that responsibility for private obligations is not properly imputable to governments, except where there is a specific government guarantee. Certain circumstances might arise, however,

[38] The proportion differs considerably for different countries, according to the scattered information which can be derived from evidence on gold holdings and central bank holdings. In the case of some countries, the writer has been able to get no information at all. However, since gold is mostly owned by governments and central banks, and securities by private owners, with banking funds split between the two, and since fairly accurate estimates of these types of holdings are available, the proportion here would seem at least not unreasonable. Central bank funds were here arbitrarily counted as public in nature, although there is considerable question whether for other purposes central banks are to be regarded as public or private institutions.

[39] This figure includes loans guaranteed by foreign governments and obligations of municipal and provincial governments, as well as the direct debts of national governments. The inclusion of municipal and provincial obligations, which total 82 million dollars, is admittedly arbitrary. See P. D. Dickens, "Status of United States Investments in Foreign Dollar Bonds, End of 1940," *For. Comm. Weekly,* July 19, 1941, p. 3.

which would render government responsibility for private commitments more reasonable. This would be the case if governments adopted (or continued) exchange controls which in effect appropriate the foreign assets of their private citizens. Under such circumstances, governments might be considered to be assuming responsibility for the debts of their private citizens, even though the privately-owned assets which the governments appropriate do not belong to that group of private citizens against whom Americans have claims. The controlling governments would then be chargeable with preventing private debtors from making payments. If such circumstances should apply to all the countries whose funds are now frozen in the United States, the possible clearance, country by country, would be 1.2 billion dollars, approximately the figure (1.5 billions) obtained above by excluding frozen private assets, but including the old war debts. Inclusion of both war debts and private claims of the United States does not materially increase clearance possibilities since either one exhausts the major portion of the available funds in this country.

It is not possible to make a defensible estimate of assets of private foreign debtors in this country which might be available for satisfaction of their obligations to us. It seems unlikely that the amount represents any substantial portion of the frozen funds, however. For instance, foreign exporters would typically own funds here, whereas foreign importers would owe debts. Only governments may be expected to be debtors and creditors of the United States at the same time.

We may conclude, then, that (1) in the unlikely case Germany should succeed in dominating Europe, and we should counter with a seizure of the frozen assets of that entire area, making these assets available for the satisfaction of American claims of all types, the clearing process would operate at maximum efficiency. It would dispose of 4.6 billion dollars of the frozen funds. (2) If, however, European countries are restored to their former national status at the end of the war, the maximum clearance (country by country) would be 3.2 billions; but this amount would probably be reduced to practically nothing by weeding out both the American claims and the foreign funds thought to be inappropriately included in the clearing.

In general the clearance of claims is unattractive, even apart from the limitations the figures indicate, because it arbitrarily singles out a limited area of the world for a forced settlement of claims, while neglecting such important areas as the British Empire and Latin America. Moreover, it is at best a procedure that would contribute greatly to the further economic segmentation of the world. As such, it would complicate, or even be utterly incompatible with, plans for the reconstruction of war-blighted countries.

The frozen funds in planned reconstruction. The perplexing problem in the post-war handling of foreign funds concerns not so much their equitable liquidation as their effective re-utilization in the processes of international finance. For the reasons expressed above, there is at least a strong possibility that unqualified removal of the controls, or removal conditioned on a reciprocal clearance of claims, would result in the extinction of all international balances—a process roughly amounting to the winding-up of the mechanism of international finance. Consequently, either of these alternatives would deal a severe blow to hopes that an adequate pattern of world finance might be constructed out of the remains of the inadequate pre-war system. The problem, then, is how to qualify the post-war release of funds so as to avoid these objections.

Basically the function of international finance, of which the foreign claims in every nation are an important aspect, is to provide international economic development with what we may describe as flexibility in time and space. Time flexibility in a system of finance permits the development of any given area of the world at a rate faster than the savings of that area would allow. Space flexibility gives facility for transferring savings from one area to any other. During the present world war, pressing needs for the greatest possible expansion of armaments plus the strategic advisability of isolating enemies and unfriendly powers reduce flexibility to a very low degree. But, what is more relevant to our purposes, even before the war the financial system had an intolerably low degree of flexibility, owing to factors too familiar to justify recital here.

At this distance from the circumstances attending the return of peace, it is difficult to speak concretely of the precise rôle which the now frozen foreign funds may be suited to play in a program of remedying the inflexibility of world finance. It is obvious that controls which operate as virtual embargoes on the movement of funds reduce flexibility. Similarly, the existence of a huge volume of defaulted international debts reduces it, as do unstable currencies. But it would be a serious error to suppose that all exchange controls, other than limited governmental operations to smooth out currency fluctuations, must be inimical to flexibility. For, despite the abstruse and extensive political manipulation of exchange controls in the last decade, there seems to be little hope of preventing defaulted debts, capital embargoes, or currency instabilities without a very appreciable degree of government control.[40]

[40] Probably few economists would care to defend the abuses of exchange controls, just as few would care to defend the financial abuses which inaugurated the era of exchange controls. Ellis apparently fears that the discriminatory possibilities in exchange control practice cannot be avoided. (*Op. cit.*, p. 217.) The danger cannot be glossed over. It

The vast movement of international funds to the United States after 1934 was unquestionably a manifestation of chronic disorder in international finance. Even so, the movement may prove to have been not entirely unhappy for the eventual reconstruction of finance. By unprecedented pooling of financial reserves in a single center, the movement may prove to have facilitated opportunely the development of a nucleus for world banking. Moreover, the movement has given to the United States increased influence in the use of international funds in the reconstruction of finance along liberal lines.[41] Thus, for example, the United States might advantageously release funds for expenditures on American goods on the condition that the beneficiary countries agree to maintain minimum gold balances in New York, or subscribe to an agreed amount of capital stock in a bank specially created to facilitate short- and long-term capital movements among the member countries.

Without a planned reconstruction, any attempt to release the frozen foreign funds will worsen the condition of international finance, proving at the same time to be very costly to the United States. But in a planned reconstruction, the problem of the frozen funds largely disappears. For example, once a means of international banking is reconstituted, there would no longer be any reason to fear the effect of allowing the owners of frozen funds substantial freedom within the agreed rules. There still might be a considerable movement to convert dollars into goods, but this movement would proceed from the actual post-war need for goods, and not from the need to dispose of international funds that have lost their significance outside of this country. Nor would it any longer be unlikely that a good portion of the funds would be withdrawn in the form of gold (assuming, of course, that the new agreements retain gold as an international money). For gold could again have a useful function in defining currency relations, securing legitimate adjustments in balances of payments, and even as a familiar basis for the control of domestic currencies.

It would be pointless to understate the difficulties which beset such a program. It involves the articulation of currencies weakened not only by unproductive foreign debts and depressed world agricultural prices, but even more by the strains of war itself, both by distortions in the

---

seems scarcely realistic to entertain the possibility of government controls aimed at international monetary stabilization without also recognizing the same opportunities for discriminatory practice. *Cf.* Tasca's account of the development of British bilateralism. (*Op. cit.*, pp. 145-57.) At the same time, there is no reason why international controls should not prove capable of avoiding both discrimination and instability. *Cf.* Virgil Salera's account of Argentine exchange control experience. (*Exchange Control and the Argentine Market* [New York, 1941], chap. XI.)

[41] By "liberal lines" is meant a system of finance which avoids the arbitrary groupings of regions on political rather than economic bases.

balance of payments and by inflationary methods of armaments finance. It further involves conceptions of international responsibility and co-operation which are quite at odds with the nationalistic developments of the past decade. It may provoke opposition among private bankers, who, though not in a position to provide the necessary institutions for a flexible world finance, none the less feel that they must resist the advent of government in their field. They contend that such a program would put finance at the mercy of politics, or more concretely and frankly, that it would deprive them of an established source of revenue.

In conclusion, then, we may say that, in deciding what policy to follow with respect to the frozen foreign funds, when the return of peace removes the reasons for their freezing, the United States must recognize its relation to the whole problem of financial reconstruction. The release of the funds is vastly more complicated than was commonly supposed at the time of their freezing. At the same time, the size of frozen holdings in the United States provides a real opportunity to influence world finance in the direction of an inclusive and flexible system, and away from unrelated arrangements between pairs of nations or among small groups of nations. Just as the war called a halt to the chronic disorders of pre-war finance, so the end of the war will provide an occasion, not soon to come again, for the long-overdue revisions in international finance. The unusual position of the United States at the end of the war, both as the trustee of a very large portion of international funds and as the only large nation in a position to finance reconstruction, could provide the means of taking advantage of that occasion in the interest of more flexible and stable world finance.

STATISTICAL INVESTIGATIONS OF SAVING, CONSUMPTION, AND INVESTMENT

By Mordecai Ezekiel

II. Investment, National Income, and the Saving-Investment Equilibrium

In the first article of this series we dealt with the functional relation between national income and saving or consumption as derived from statistical analysis of data for the United States covering the past two decades.[1] The hypotheses tested in the last article were:

1. Saving is a function of the current level of income, increasing as the level of income increases, but at a higher rate.
2. Consumption is a function of the current level of net income, increasing as the level of income increases, but at a lower rate than income.
3. The patterns of thrift, expenditure, and consumption at any given level of income are habitual patterns of action, changing only gradually in time, so that changes in current income received by each group produce reasonably consistent changes in total consumption and saving.

In this article we shall examine for the same period the apparent relation of investment to income while holding constant, where possible, the effects of other related factors. Since by our definition in any one year total investment equals total saving, the over-all relation must be the same as that already shown in Figures 4 and 5 of the previous article. This presents a difficulty which is similar to that of attempting to derive both a demand curve and a supply curve from a series of prices and quantities. However, we may gain a much better understanding of how the yearly equilibrium of total saving and investment happens to have been struck at the levels of gross national income prevailing during each of the past twenty years if we look further into the component elements of investment and how they are related to income and other factors.

In addition to studying the behavior of investment under the fluctuating conditions of the past twenty years, we shall also investigate what

[1] Mordecai Ezekiel, "Statistical Investigations of Saving, Consumption, and Investment—Part I: Saving, Consumption, and National Income," *Am. Econ. Rev.*, vol. xxxii, March, 1942, pp. 22-49. Acknowledgment in this, as in the previous article, is due to John Maynard Keynes, Alvin H. Hansen, Gerhard Colm, Walter S. Salant, Hans P. Neisser, A. Smithies, and Paul A. Samuelson, for many valuable suggestions and comments, and to Virginia R. Duncan for the compilation and statistical analyses of this study and for bringing together and abstracting the bibliographical material.

investment would be likely to be more under stable conditions if our economy were operating at a steadily increasing rate of production and income.

The hypotheses which we propose to test here may be stated as follows:

1. If investment is broken down into its various components, the relation to the level of income will vary from item to item. Examination of these separate relations will yield some explanation for the past behavior of income and employment.

2. Investment expenditures are related to certain independent factors, such as the anticipation of future returns and the rate of interest, and others, which examination of the separate components will more clearly reveal.

3. As income rises the increase in potential saving has been more rapid than the increase in potential private investment, and the point at which the two could be in equilibrium has been materially below a level of full employment and production.

4. The levels of investment which could be maintained at full employment with a steadily rising level of national income would differ materially from those which have prevailed during the temporary periods of full employment under past widely fluctuating conditions.

From the analysis in Section A which follows we derive what might be called an "apparent investment-income function" under the conditions of the past twenty years. Comparison of this function with the saving function (Section B) presented in the previous article indicates the levels of income at which saving and investment presumably would have been in equilibrium during the 1920's and 1930's, had there not been investment expenditures which were independent of our private domestic economy. The first two sections of the paper present, then, a study of the behavior of income, investment, and saving under the cyclical conditions existing during the past two decades. The third section of this article attempts to develop the long-term normal investment function—to estimate the investment which would be necessary to maintain a gradually but steadily rising level of full production and employment, while allowing for population growth and technological development. This function may then be compared with the saving function as determined under the institutional patterns of the past two decades to give a measurement of the "gap" between potential saving and potential private investment which would remain to be closed in the post-war period if the national income were maintained at substantially full levels of production and employment, while providing for the expanding population and for continuing increase in productivity.

A. *The Apparent Investment-Income Relation under the Fluctuating Conditions of the Past Two Decades*

Types of Investment

The data on offsets to saving, or income-producing expenditures, were presented in detail in the first article of this series. They are again listed here in Table I. These data may be classified into three groups with respect to their significance from the investment point of view:

Long-term or permanent private investment includes items of private expenditure for all durable producers' capital goods, plus expenditures (either commercially for profit or by individuals for their own use) for housing. Such expenditures cover what classical economists and most business men think of when they speak of "investment." One distinguishing feature of such investment is that it can never be negative.[2] Even in the worst year, 1932, expenditures for long-term permanent private investment totaled 2.0 billion dollars.

Short-term or temporary private investment includes those items of private investment where increases in some periods may be offset by decreases in others. In a stationary society, the total over a term of years would tend to be zero. (Even in a stationary society, long-term investment in contrast would have to equal in amount average depreciation and depletion.) Changes in consumers' credit and in inventories fall in this category.

Over the twenty years from 1921 to 1940 the average annual increase in consumers' credit was only 313 million dollars, and the average annual increase in inventories only 530 millions, yet consumers' credit varied through an amplitude from —1,485 millions to +1,046, and inventory changes from —2,278 to +2,964. While contributing very little to investment on the average, these items of temporary private investment did constitute exceedingly volatile and unstable items in individual years or periods.

Quasi-investment is a complex concept which must be introduced carefully. Both types of private investment, permanent and temporary, are largely conscious investment, in that they result from the deliberate decision of individuals or concerns to buy capital goods, or to buy consumers' goods financed through credit as if they were capital goods.[3] Beyond this investment due to the decision of private individuals or business concerns are items of investment which reflect institutions that

[2] Net investment can of course be negative when depreciation exceeds replacement. We are dealing here, however, with gross national income and gross capital formation. Physical production of plant and equipment can never be less than zero.

[3] This has the single exception that at times increases in inventories may represent involuntary investment, due to a contraction in market outlets after production has been gotten under way.

TABLE I—GROSS NATIONAL INCOME AND INCOME-PRODUCING EXPENDITURES THAT OFFSET SAVING, BY YEARS, 1921–40

(In millions of dollars)

Year	Gross National Income	Income-Producing Expenditures that Offset Saving							
		Total	Equipment	Plant	Housing	Consumers' Credit	Net Foreign Balance	Inventories	Government Net Contribution[b]
1921	63,751	9,548	2,758	2,475	2,313	−20[a]	1,327	47	648
1922	64,295	11,870	3,140	2,644	3,801	730[a]	293	514	748
1923	74,784	16,990	4,622	3,280	4,821	1,046[a]	−91	2,964	348
1924	75,161	13,279	4,343	3,307	5,229	311	530	−1,056	615
1925	79,686	17,032	4,598	3,591	5,750	842	199	1,523	529
1926	84,813	16,760	4,941	4,185	5,535	648	−39	1,246	244

1940	82,000[a]	17,580	5,751	2,360	2,431	1,014	1,417	733	3,874

[a] Estimated.

[b] Omits state and local net contribution from 1929 on.

NOTE: For sources and methods, see statement submitted to the Temporary National Economic Committee by Lauchlin Currie on May 16, 1939 (Hearings before the Temporary National Economic Committee, Pt. 9, *Savings and Investment*). See also Oscar L. Altman, *Saving, Investment, and National Income*, T.N.E.C. monog. no. 37 (Washington, Supt. Docs., 1941). These data are revisions of those previously published.

lie largely outside the private domestic economy as such. These items are summarized in the two categories of net foreign balance and of government net contribution. If it were not for the intervention of the government through tariffs and other trade restrictions (and possibly of private business through export dumping and other forms of forcing exports) the net foreign balance, like the items of temporary investment, would tend to average out near zero over a long term of years.[4]

[4] Keynes has shown clearly that maintenance of a large and continuous positive net foreign balance is a form of economic warfare and one of the causes of international warfare. His discussion here seems to suggest the further conclusion that in a stable and peaceful world, where every country had equal opportunity to maintain the employment and increase the welfare of its citizens, net foreign balances would tend to average out at zero

The government net contribution is the final balancing factor between saving and investment. Although public expenditures contain some elements of public or social investment, they also include at times large amounts for relief, old-age grants, farm benefits, defense or military expenditures, and similar items which do not represent the purchase of capital goods. Furthermore, when public works (as the schools or roads built in the 1920's) are in part paid for concurrently from taxes levied on commodities, or which otherwise directly reduce consumers' expenditures for their own consumption, the purchase of real capital goods by public agencies is partly offset by the reduction of consumption purchases by individuals, and so does not use up savings. For these reasons (which are discussed at more length in the basic studies on the subject)[5] the net (adjusted) difference between government re-

over long periods of time. J. M. Keynes, *The General Theory of Employment, Interest, and Money* (New York, Harcourt Brace, 1935), pp. 333-51.

[5] Testimony by Lauchlin Currie, Hearings before the Temporary National Economic Committee, Pt. 9, *Savings and Investment* (Washington, Supt. Docs., 1940), pp. 3528-29, 4017.

ceipts and government expenditures, although it must be regarded as an offset to saving, cannot be regarded as investment in the conventional sense of expenditure for capital goods.

Net foreign balance and net government contribution are thus items that offset saving in ways quite different from the traditional concept of direct purchase of real capital goods. For that reason, the term *quasi-investment* will be used here to designate the sum of these two items.[6]

The annual investment expenditures, broken down into these three groups, are summarized in Table II.

When these three elements of investment and gross national income are charted (Figure 1), the differences in their behavior are marked. Permanent private investment and national income vary concurrently, with the relative magnitude of variation much higher in investment. Temporary private investment on the contrary tends to be negative in amount during periods of constant or declining business activity. Permanent private investment is apparently associated primarily with the *amount* of national income; temporary private investment, primarily with the *rate of change* of national income.

The extent to which private investment is related to national income is shown more closely in Figure 2. Here the two components, permanent and temporary, are plotted on two dot charts with national income as the other variable. The general positive relation is quite marked, especially for permanent investment. It is clear that national income (or the level of business activity or anticipations which it reflects or engenders) is closely associated with both permanent and temporary investment.

The relation of quasi-investment to national income (Figure 3) has been quite different. From 1921 to 1933 there was a slight negative correlation.[7] Since 1934, with much larger volumes of net government contribution, the correlation has been generally positive, though 1937 falls far out of line with the other observations for this period.

In view of the dissimilarity of behavior, the factors related to permanent private investment and temporary private investment will be examined separately.

[6] Gerhard Colm has suggested that the breakdown of investment into permanent or long-term, temporary or short-term, and quasi-investment might well be extended to saving as well, with particular reference to quasi-saving and quasi-dissaving. Inasmuch as the available data on the makeup of saving are not nearly as adequate as the data on the components of investment, we have not attempted to carry this suggestion through for the present. Salant suggests that the behavior of each of the separate components of quasi-investment, imports, exports, adjusted government receipts, and adjusted government expenditures, might well be studied separately. This has not been attempted in this over-all survey, but is left for subsequent more detailed analyses.

[7] This may have been due to the tendency of government revenue (which is a negative component of net government contribution) to rise with national income, while total expenditures remained relatively constant.

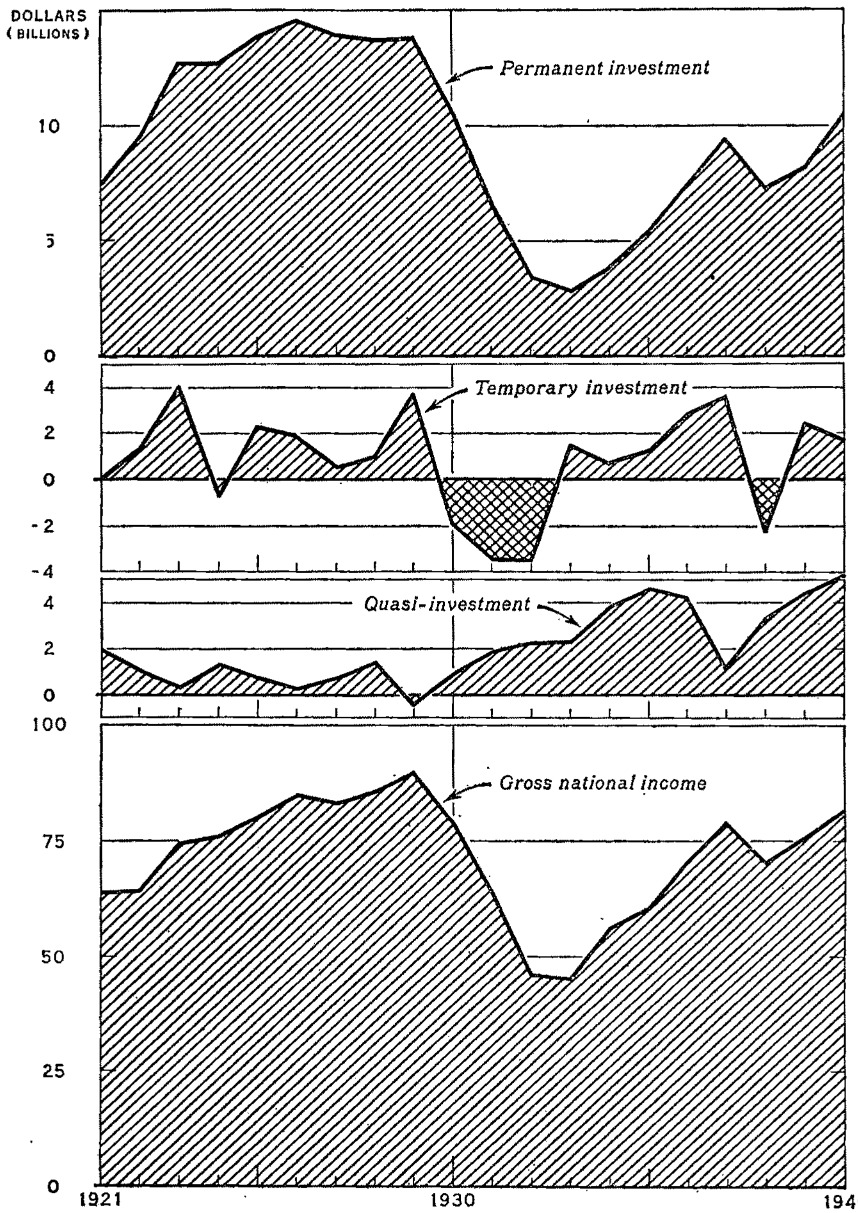

FIG. 1—Investment Components and National Income, 1921-40.

Permanent Private Investment and National Income

Permanent private investment for a given national income was high from 1922 to 1925. Thereafter, permanent investment showed no further increase as national income increased to 1929, indicating a down-

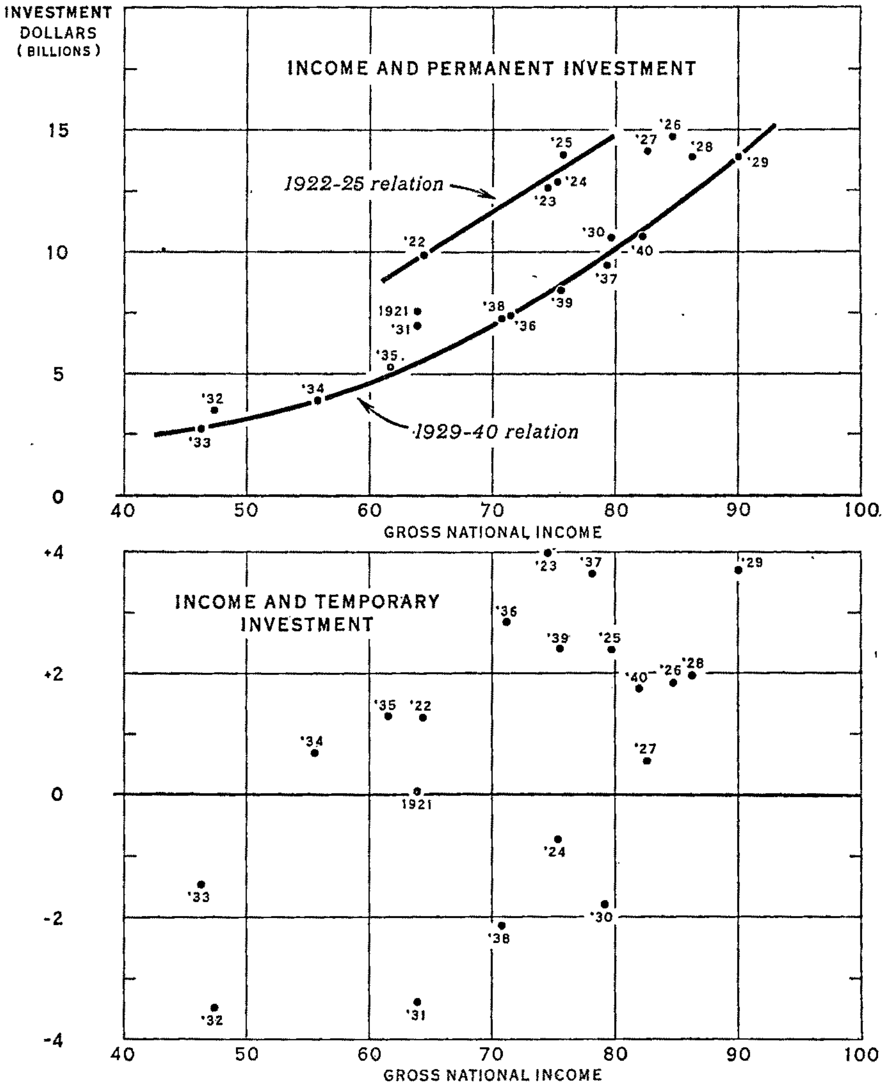

FIG. 2—Private Investment and National Income.

ward shift in the relation of investment to income. Since 1929, permanent investment has varied quite consistently with national income along the line indicated by the lower curved line drawn in free-hand in Figure 2.

This shift in the relation of permanent private investment to national income apparently occurred between 1925 and 1929, and therefore cannot be ascribed to the influence of New Deal legislation or of changes

in "business confidence" often alleged to be associated therewith. It can be explained, however, if we separate housing from other forms of permanent investment (plant and equipment expenditures). These data are given in Table III. This table shows the well-known drop in housing expenditures during the 1930's. It also shows that other items of permanent investment ran nearly as high from 1936 through 1940 as during the 1920's.

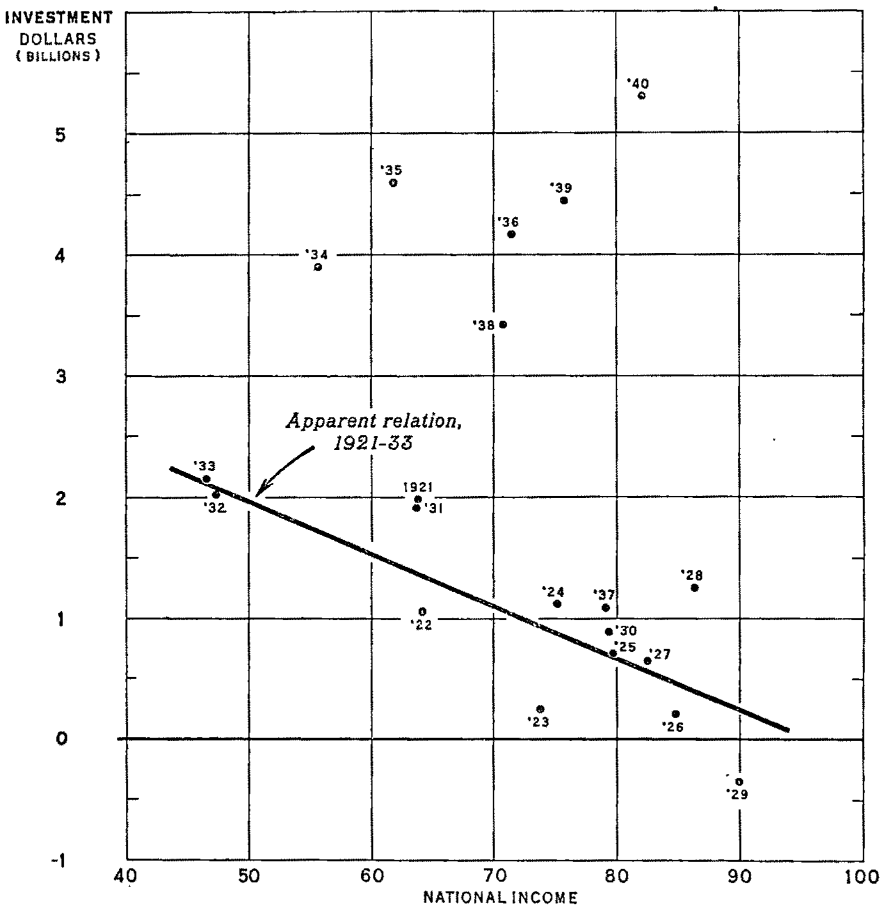

FIG. 3—Quasi-Investment and National Income.

The relation between each of these two categories of permanent investment and national income is indicated in Figure 4. There is some correlation between housing investment and national income (shown on the upper half), but the level of housing investment accompanying

the same national income was more than twice as high in the middle 1920's as it was in the 1930's. Plant and equipment investment, on the contrary (on the lower half), apparently varied closely with national income over both decades.

Plant and equipment expenditure: (a) Related to prior conditions. Economic theory has always held that business men build plant and equipment when they expect that the investment will yield them a profit, and cease building when the expectation of profit vanishes. Any statistical measurement of the conformity of fact with this theory depends upon finding objective indicators of business men's anticipations. In farming, the evidence is very clear that producers (in the absence of governmental controls) take the prices received in the preceding production period or periods as the best indicator of the prices they are likely to receive in the coming production period, and adjust their operations accordingly.[8] If the psychology of business men is similar, they might be expected to base their expectations of future profits, and hence their new investment, on the level of profit or the level of operations in the period just completed, or perhaps on the rate at which those

levels were changing. Similarly, if interest rates do have any influence on business investment decisions, business men might react to the relation of profit rate to interest rate, rather than to profit rate alone.

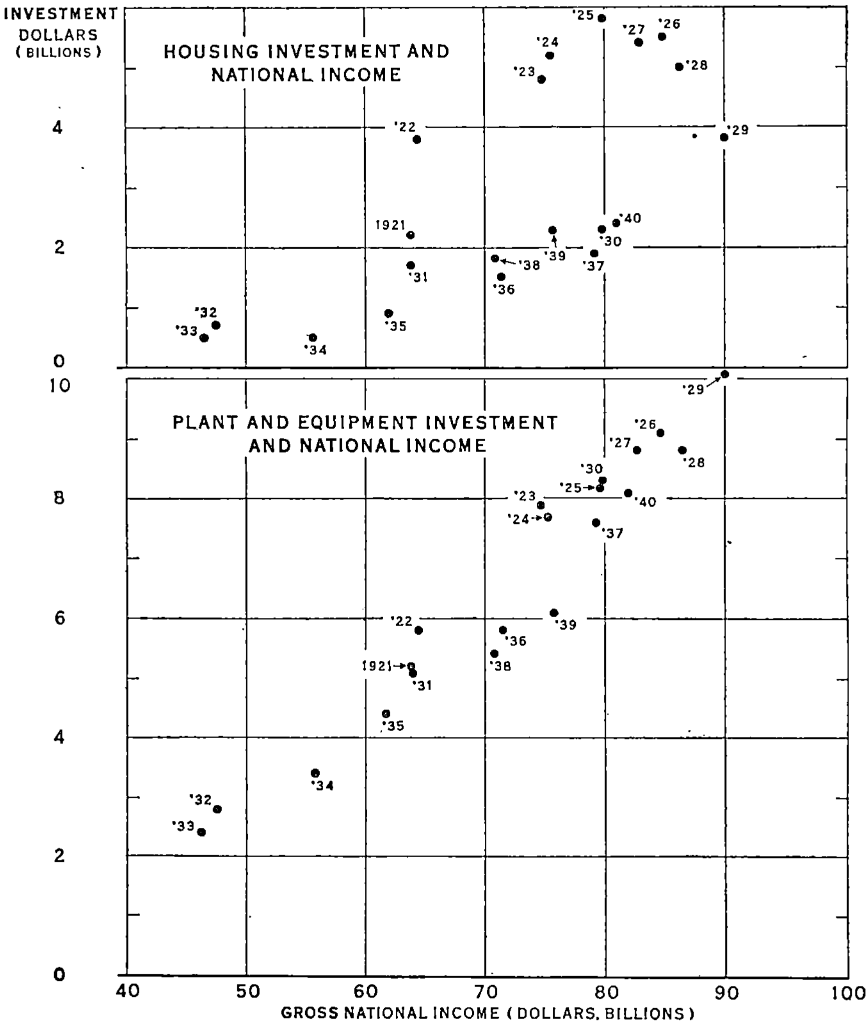

FIG. 4—Two Components of Permanent Investment and National Income.

A large number of tests were made to see if any such relation could be found between business activity or profits and subsequent investment in producers' equipment. The most significant relation discovered was that between corporate profits in one year and plant and equipment investment in the following year. About four-fifths of the variation in

investment was explained by this simple relation.[9] Profits expressed as a percentage of net worth proved less significant than total profits. Inclusion of interest rates, by expressing profit rate relative to the long-time rate of interest (as shown by corporate bond yields) did not improve the relationship significantly. This confirmed several other tests of the effect of interest rates—no significant influence of interest on investment was found in any of the tests.[10] Statistical investigations of business cycle phenomena in Britain yielded the same result, that the rate of interest has not been an important determinant of investment activity.[11]

The data indicate that current conditions as well as antecedent conditions influence business investment. Thus in some years when business activity contracted sharply during the year, as in 1930 and 1938, investment fell off by much more than would have been expected from the profits of the preceding year. When profits of both the preceding and the current year are taken into account, over nine-tenths of the variation in investment could be explained, with profits of the preceding year having a weight almost 50 per cent heavier than the profits of the current year.[12]

[9] The data on profits were the corporate profits before taxes, as given in Martin Taitel, *Profits, Productive Activities, and New Investment,* T.N.E.C. monog. no. 12 (Washington, Supt. Docs., 1941), p. 23. The correlation was $\bar{R}^2_{12} = 0.825$. There was no secular change in the relation—inclusion of a trend factor increased the correlation only to $\bar{R}^2_{1.23} = 0.827$, an increase without statistical significance.

[10] On this point, J. M. Keynes comments: "I am far from fully convinced by the recent thesis that interest rates play a small part in determining the volume of investment. It may be that other influences, such as an increase in demand, often dominate it in starting a movement. But I am quite unconvinced that low interest rates cannot play an enormous part in sustaining investment at a given figure, and when there is a movement from a higher rate to a lower rate in allowing a greater scale of investment to proceed over a very much longer period than would otherwise be possible." In conversation, Keynes has explained his point further by saying that we have never really tried what the effect would be of a very low interest rate, made available to the actual borrowers over a long period. In view of the many institutional factors which Keynes develops (*op. cit.*, pp. 194-209) to explain why actual rates to borrowers never have, and perhaps never will, fall to the very low rates he feels are desirable and necessary, the question as to what would happen if they could be held there may remain purely a theoretical problem for a long time ahead.

[11] E. A. Radice, "A Dynamic Scheme for the British Trade Cycle, 1929-37," *Econometrica,* Jan., 1939, p. 49.

[12] The relationship determined was

$$X_{1(t_0)} = 4.428 + .248X_{2(t_0)} + .332X_{2(t_{-1})} + .012T$$

where $X_{1(t_0)}$ = plant and equipment expenditures, in billions

$X_{2(t_0)}$ = corporate net profit before taxes of the current year, in billions

$X_{2(t_{-1})}$ = corporate net profit before taxes of the preceding year, in billions

T = time, in years

For the twenty years 1921-1940, the correlation was $\bar{R}^2 = .920$, and the standard error of estimate, $\bar{S} = 625$ millions.

Current business levels apparently condition or limit the extent to which prior investment decisions are carried into effect.[13] Half to two-thirds of expenditures for plant and equipment are for replacement rather than for new investment. These replacement expenditures may be even more sharply influenced by current conditions than are plant expansion programs.[14]

Plant and equipment expenditure: (b) Related to current conditions. Business investment is less closely related to current profits than it is to earlier profits. But when business investment is related to the current level of national income, a very close relation is found. (See Figure 4, lower section.) This relation is particularly close when allowance is made for the apparent downward shift evident in Figure 4. Taking both current national income and this downward trend into account, all except 1½ per cent of the variation in investment can be explained by this relation.[15] (Note Figure 5.) This high correlation by itself does not prove either that business investment *causes* national income, or that national income *causes* investment. In fact, as we have just seen, prior profits have a logical and measurable causal influence on investment. The effect of subsequent developments as a limiting factor on investment, however, is apparently very high. Current national income depends upon many factors other than business investment alone. The very high concurrent relation between income and investment indicates that this conditioning or limiting influence of current income upon business investment is a very powerful one.[16]

The downward trend in investment at given levels of current national

[13] These conclusions are confirmed by quarterly data on manufacturers' profits and investment, as given by Lowell J. Chawner, in "Capital Expenditures for Manufacturing Plant and Equipment, 1915-1940," *Survey of Current Business*, vol. xxi, March, 1941. His chart (p. 13) shows that factory capital expenditures usually start to expand *after* an upturn in net profits, but almost always begin to contract as soon as profits turn down.

[14] It would undoubtedly be profitable to make separate studies of plant and equipment expenditures for new capital goods and those for replacement of existing capital goods. This has not been attempted in the present article because of the many technical difficulties in making an accurate division between new capital goods and replacement.

[15] Figure 5 shows the net regression lines obtained by a multiple correlation analysis using the formula, Investment $= f(\text{Income}) + b(\text{Time})$. The curve and trend line were fitted by the graphic successive approximation method. The multiple curvilinear correlation was $P^2 = .985$, and the standard error of estimate 270 million dollars. The curvilinear multiple correlation was found to be significantly higher than the linear multiple correlation. The relation to the two factors explains 98 per cent of the variance in plant and equipment expenditure.

[16] The relation between national income and business investment is quite different from that between national income and total investment or saving, as measured in the preceding article. The dynamic elements present in the latter relation do not appear in the present one. The relation to business investment does not therefore seem to be in any way fortuitous or spurious.

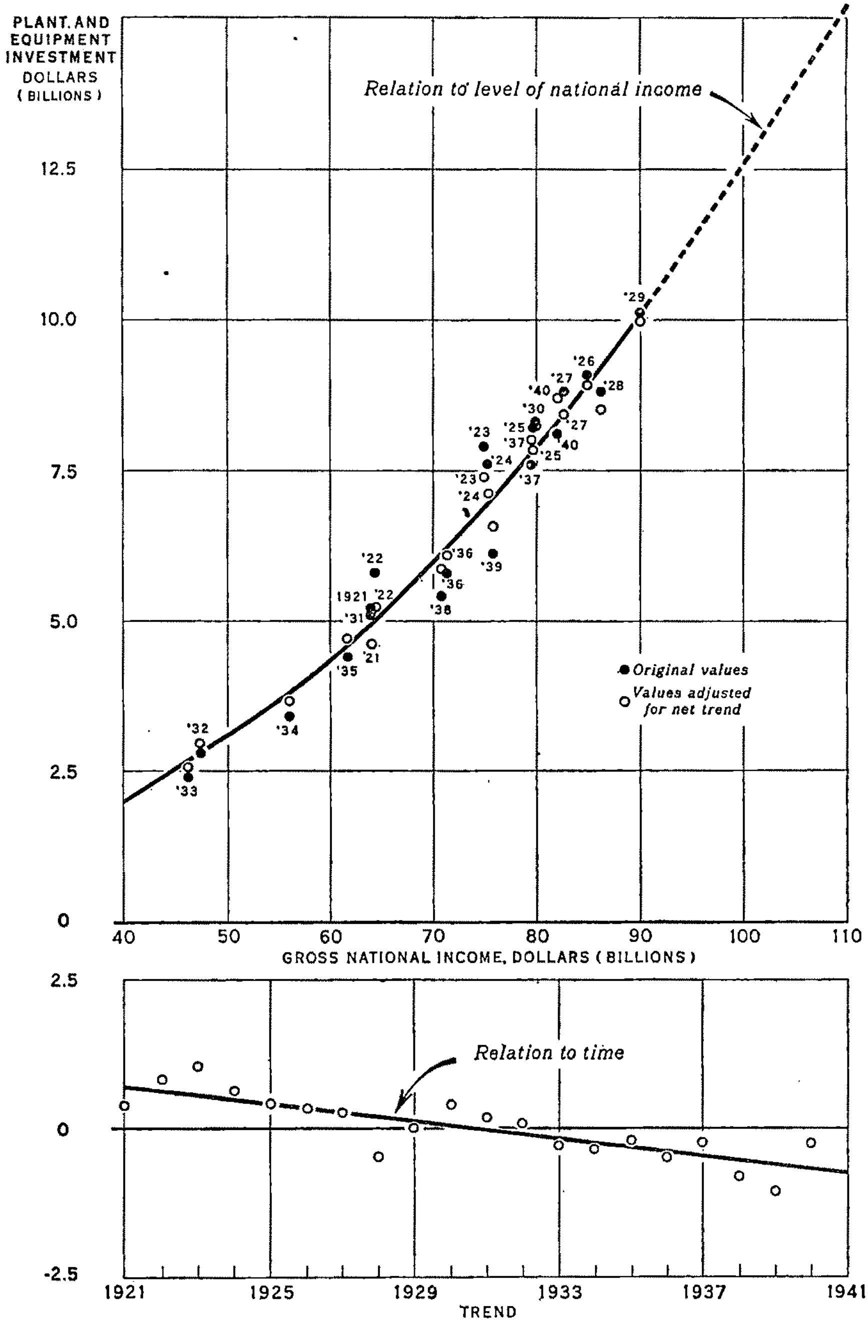

FIG. 5—Factors Related to Plant and Equipment Expenditures, 1921-40.

income may reflect the decline in the rate of population growth, with consequent slowing down in the entire rate of national industrial expansion. An alternative explanation relates to the cost and durability of machinery. Better steels, better design, and improvements in the efficiency of machine tools may make it possible to get the same productive power with a constantly declining cash investment, just as the real cost of automobile transportation has had a definite downward trend. To the extent this is so, a declining proportion of the national income may be sufficient to produce the same net increase in producers' equipment.[17]

This over-all analysis may cover up diverse relations of activity to business investment which characterize individual industries. An industry-by-industry analysis of the relations would clear up this possibility. In such a detailed analysis it might also be possible to take into account the total stock of capital goods in each industry and the degree of utilization of existing capacity, to determine the marginal efficiency of additional plant and equipment. Thus, in the electric power industry, superficial examination of the data suggests that the relation between current capacity and current output is a major factor influencing plant expansion, with a large and rapid expansion following each period when current output begins to press closely upon installed capacity.

New capital expenditures may of course originate independently of the factors which we have used in making analyses. The development of new industries and new products seems to have been an important determinant of the level of these expenditures in the past. Such factors apparently were not of major importance during the period under study.

Business investment thus seems to be related both to previous changes in profits, and to current changes in national income. As will be shown subsequently, other types of investment are dynamically related to income changes. With these concurrent and lagging relations, it would be possible to set up a realistic dynamic model which would reproduce the general patterns of the continuous fluctuations of the past twenty years. That has not been attempted in this article.[18]

Housing investment. Housing investment is apparently related to forces other than the current national income. These forces can be separated by fitting a trend to the relation shown in the upper portion of Figure 4, and determining how much of the variation can be ex-

[17] Dr. Colm suggests that the development from "competitive" investments to "administered" investments, based on scientific analysis of the market which usually takes under consideration only existing factors and not anticipated expansion in total national income and demand, has something to do with the downward trend in investment.

[18] For examples of such dynamic models, see J. Tinbergen, *An Econometric Approach to Business-Cycle Problems* (Paris, Hermann, 1937); and E. A. Radice, *op. cit.*

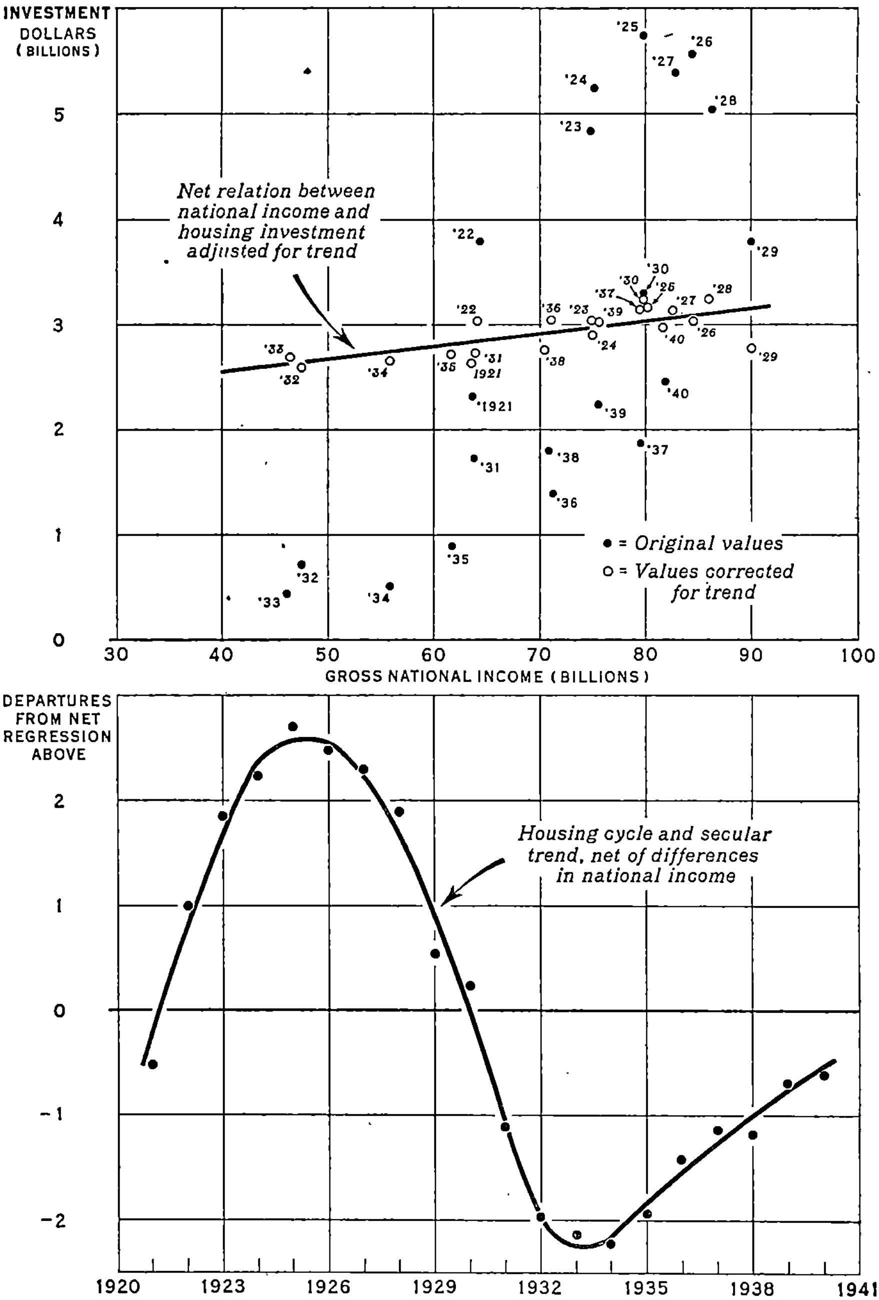

FIG. 6—Factors Associated with Housing Investment.

plained by national income while the secular trend factors are simultaneously held constant. The results secured by this analysis (made by graphic multiple correlation) are shown in Figure 6.

It has been well established that the housing cycle is in part self-generating, and operates partially independently of concurrent changes in industrial activity.[19] If the net trend in the lower portion of Figure 6 is taken as representing the influence of this semi-independent housing cycle upon housing investment, then the net regression line shown in the upper portion would represent the net influence of gross national income upon housing investment while the influence of the long-time housing cycle is held constant at its mean level.[20] The lower level of the trend during the housing recovery in the thirties may reflect the lower price level and also technological changes in the housing industry, with smaller houses and lower costs per dwelling unit.

The net housing cycle shown in the lower portion of Figure 6 offers an interesting comparison with the net trends in the levels of the saving and investment functions, as shown in the lower portions of Figures 6 and 9 of the preceding article. The housing and saving trends were high in the twenties, declining in the late twenties, very low in the early thirties, and rising in the late thirties. These similarities of movement suggest that differences in the phase of the housing cycle may influence the levels of saving and consumption as well as of investment. The way new housing is financed largely by sale to individual families upon the amortization plan may mean that purchase of a home puts increased pressure on a family to save even with no change in income level.[21]

The relations shown in Figures 5 and 6 can now be consolidated to show the net change in private investment in the twenties and in the thirties which was associated with differences in the level of gross national income. In making these calculations, the housing investment is adjusted to the average level of the housing cycle in each of the two decades, and plant and equipment investment is adjusted for the average of trend in each decade. The results are as follows:

[19] Clarence D. Lang, "Long Cycles in Building, 1865-1935," *Quart. Jour. of Econ.*, vol. liii, May, 1939, pp. 371-403. J. B. D. Derksen, "Long Cycles in Residential Building: An Explanation," *Econometrica*, vol. 8, April, 1940, pp. 97-116.

[20] The intercorrelation between time and the national income values is so high in this period that there is little statistical reliability in the measurement of these two net regressions. In preparing Figure 6, the slope of the net regression of housing investment on national income could be drawn considerably steeper with equal closeness of fit. The statistical evidence here is thus not conclusive as to how far housing investment depends on national income, and how far on independent elements of the housing cycle.

[21] Keynes's remarks about the effect of Building Societies' sinking-funds on savings are interesting in this connection. *Op. cit.*, p. 101.

TABLE A—CALCULATION OF PRIVATE PERMANENT INVESTMENT ASSOCIATED WITH VARIOUS LEVELS OF NATIONAL INCOME

(In billions of dollars)

Gross National Income	1920 Decade			1930 Decade		
	Plant and Equipment[a]	Housing[b]	Total	Plant and Equipment[a]	Housing[b]	Total

100	(12.95)	(4.80)	(17.75)	(12.25)	(2.15)	(14.40)
110	(15.55)	(4.95)	(20.50)	(14.85)	(2.30)	(17.15)

Trend readings for plant and equipment: average 1920's = +.35; average 1930's = −.35
Trend readings for housing: average 1920's = +1.45; average 1930's = −1.20

[a] From Figure 5.

[b] From Figure 6.

[c] Data shown in parentheses represent extrapolations beyond the range of the observations on which the relations were based.

The major influence of the phase of the housing cycle upon the level of permanent investment is clearly apparent from these calculations.

Temporary Investment and National Income

The way in which temporary investment is associated with *changes* in national income has already been pointed out in connection with Figures 1 and 2. This relation can be seen more clearly by plotting temporary investment against the change in national income from that of the previous year. This comparison is shown in Figure 7. The general relation between change in gross national income and the amount of temporary investment is striking. Temporary investment itself represents merely the *changes* in the total amount of consumer credit outstanding, and in the total amount of business inventories, so this relationship is what one might expect. Apparently variations in national income are associated with parallel variations in the totals of consumer credit and business inventories, so that the first differences in the two series have the positive correlation shown. When income is rising, the rising consumer credit and inventory volumes absorb investment funds, and thus make an outlet for saving; when income is falling, consumers pay off their credit and businesses contract their inventories, and thus release funds for other uses.[22]

[22] Keynes and Salant both suggest that combining temporary investment in consumers' goods and temporary investment in working capital may combine two elements which

Figure 7 shows that in two years—1921 and 1934—temporary investment differed greatly from other years with similar changes in income levels. The year 1921 was one of low business activity as compared with 1920. The low point in industrial activity, however, occurred in the spring, and there was a strong upward movement during the balance of the year. Despite the low level of income for the year, this advancing

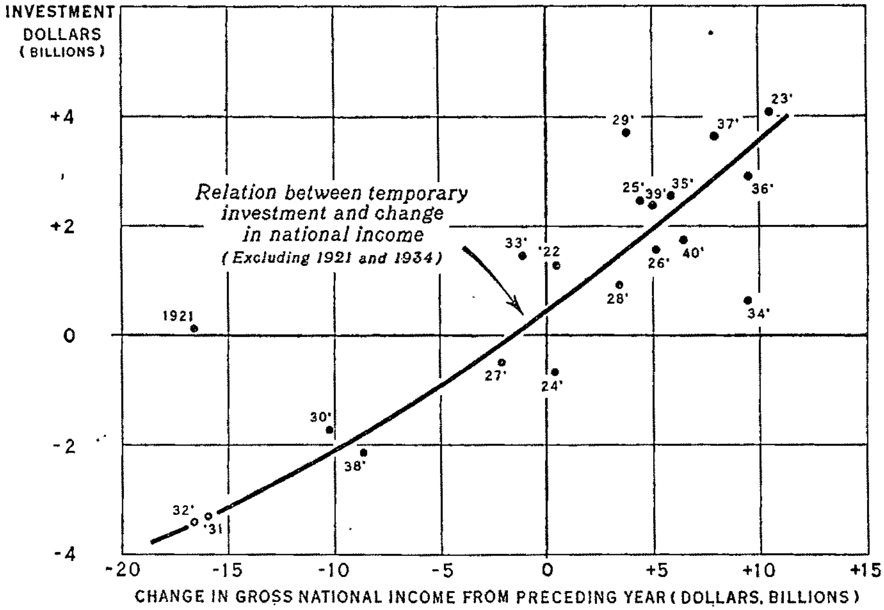

FIG. 7—Factors Associated with Temporary Investment.

---

behave in different ways and thus obscure the true facts. Keynes says, commenting on these statements: "As regards temporary investment, I think it most important to distinguish two kinds of it; namely, temporary investment or disinvestment in stocks of consumer goods and in stocks of working capital. This distinction is important because these two types of temporary investment are likely to move in opposite directions, so that the true movements are obscured if one adds them together. . . . Take the case where there has been an unforeseen increase in permanent investment. During the period of increase from one level of permanent investment to a higher level there will be an important increment of working capital. On the other hand, the increase in consumers' purchasing power, unaccompanied by any immediate comparably increased output of consumers' goods, will be accompanied by a reduction in stocks of consumers' goods. Similarly, in a period of incipient depression, working capital will fall off and stocks of consumers' goods will pile up. Thus you lose an important clue by adding these together. . . ." It is theoretically possible for the two elements of temporary investment to react in opposite directions. During the two decades under study, however, there were only two years in which the sign of the two series (plus or minus) was different, and in one of these the difference was an insignificant amount. It appears that during the period covered by this analysis the behavior of these two items of temporary investment was sufficiently similar to combine them for the sake of this over-all analysis. More detailed investigations might appropriately study the behavior of each of these components separately.

trend through most of the year apparently checked the negative temporary investment which might have been expected with the current reduced level of national income. In 1934 the situation was reversed, with a sharp decline in industrial production from spring to late fall. Apparently this six-month reaction offset part of the usual effect of the higher level of income on temporary investment.[23] Excluding these two years when erratic short-time movements disturbed the usual relation, a curve has been drawn in on Figure 7 showing the apparent average relation between changes in gross national income and the amount of temporary investment.[24]

The large amplitude of variation in temporary private investment is important. Figure 7 shows a usual swing in temporary investment from —3½ billion dollars in years of sharply declining activity to +3½ billions in years of rapid increase in income. This total swing of 7 billions in the amount of temporary investment compares with a difference of 6 billions in the amount of permanent investment as between a 60-billion dollar and a 90-billion level of national income, as shown in Table A for the decade of the 1920's. Excluding the changes in investment due to the phase of the housing cycle, and considering only those changes in private investment which vary with the level of national income itself, it appears that the swings in temporary investment are just as important in explaining the total amount of investment as are the proportionately less intense changes in permanent investment.[25]

Quasi-Investment and National Income

It has already been pointed out that Figure 3 shows a negative relation between quasi-investment and national income prior to 1934. This

[23] The relation between short-time changes in business activity and income and changes in temporary investment within the year could be determined more accurately by a study of quarterly or monthly data. These are available only back to 1929. The quarterly data for 1934 are consistent with the explanation offered above.

[24] It would be reasonable to expect that the willingness to make expenditures for additions to inventories, or through increases in consumers' credits, would be influenced by the total level of inventories and consumers' credits as well as by the changes in income. Thus if inventories were already high, business men might be less willing to increase them further than if they were low. No evidence to confirm this theory was found, however, on study of the annual data from this point of view.

[25] This analysis shows that the amplitude of temporary investment associated with the changes in income is of the same order of magnitude as the amplitude of permanent investment associated with the level of income. This fact may be of great importance in dealing with the problem as to whether the saving-investment phenomena are such as to produce a damped cycle in business activity or a continuously fluctuating cycle. On purely theoretical grounds Smithies came to the conclusion "the existence of a non-cyclical solution depends on either *A* or *B* being sufficiently great relative to the other for its effect always to dominate the situation." (His *A* and *B* reflect the static and the dynamic elements, respectively.) The realistic parameters from this empirical analysis suggest far-reaching theoretical implications, when joined with the theoretical expectations of his process analysis. See A. Smithies, "Process Analysis and Equilibrium Analysis," *Econometrica*, Jan., 1942, pp. 26-38.

negative relation apparently reflects the inflexible character of most government expenditures, at least over short periods, as compared with the immediate and automatic effects of changes in national income upon the public revenues derived from an unchanging tax structure. Net foreign balances, too, may react in somewhat the same way, since the level of our imports responds immediately to good or bad domestic business conditions, while the level of exports may not be quite so sensitive. Both of these matters require further study before definitive conclusions could be reached. Since 1933 there has been a less definite relation between the level of national income and quasi-investment. Changes in national fiscal or defense policy, rather than the impersonal effect of economic conditions, have apparently been the controlling influence in this later period. Thus 1937 and 1939, both years of about the same national income, varied by 3 billion dollars in the total of quasi-investment.

We can, however, fit a rough line to the data shown in Figure 3 for the years 1921 to 1933, and use this line as an expression of the average relation between national income and quasi-investment prior to the time that public expenditure and taxes became conscious and recognized means for government to use in influencing the levels of economic activity. This approximate regression is shown in Figure 3.

B. *The Saving-Investment Equilibrium in the 1920's and 1930's*

National Income and Corresponding Private Investment

This analysis of the three components of investment has given us, for the 1920's and 1930's, approximate measures of the amount of private investment which was associated with a given level of national income, while holding constant the other major factors related to investment —change in the level of the housing cycle, change in the level of national income itself, and quasi-investment.

Because of the major relation between *change* in national income and investment, the amount of private investment will be quite different when we consider investment at maintained or static levels of national income, or investment at changing levels of national income. Let us first calculate what private investment would have been at each of several levels of national income, on the assumption that income had remained steady at each such level for two or three years in succession. The calculations will have to be made separately for the 1920's and the 1930's, in view of the difference in the level of the housing cycle in the two periods.

If instead of making this assumption of a static level of national income, we calculated what investment would have been over a series of

TABLE B—CALCULATION OF TOTAL PRIVATE INVESTMENT AT VARIOUS STATIC LEVELS OF NATIONAL INCOME

(In billions of dollars)

Gross National Income	1920 Decade			1930 Decade

100	(17.75)	0.5	(18.25)	(14.40)	0.5	(14.90)
110	(20.50)	0.5	(21.00)	(17.15)	0.5	(17.65)

[a] From Table A.
[b] From Figure 7.
[c] Data in parentheses represent extrapolations beyond the range of the observations on which the relations were based.

years of changing income, the results would be quite different. Let us assume that income varies over a succession of years, as shown in Table C. Under the conditions of the 1920's, the associated private investment would have been as shown in Table C (see page 294).

The results in Table C illustrate how differently investment behaves when income is falling from when it is static or rising. At 80 billion dollars national income, with income declining at 10 billions a year, total private investment (in the 1920's) ran about 11 billions; at the same national income, when income was rising at the same rate, it ran about 16 billions. Comparing Table C with Table B, we see that the total private investment associated with a 70-billion level of national income with income rising at 10 billions a year is about as large as it would be at a static level of 85 billions a year.

Saving versus Private Investment

Under static conditions. We are ready now to examine hypothesis 3, on the balance between saving and investment. This involves comparing the functional relation of saving and income with the apparent functional relation of investment and income. To this point we have made rough measurements of the relations between gross national income and total saving and between national income and various types of private investment, while eliminating the influence of some of the other related factors. We have found that dynamic elements as well as static elements are present in both the relation to saving and the relation to

investment. We can compare the saving function with the apparent investment function on either a static basis or a dynamic basis. Let us first consider the static relations.

Table B shows the usual private investment which upon the basis of data for the past twenty years would accompany various static levels of national income. Let us now compare that with the usual total saving made at the same static levels of national income, according to the relations shown in Figure 6 of Part I. Since we calculated our investment

TABLE C—CALCULATION OF PRIVATE INVESTMENT AT VARIOUS DYNAMIC LEVELS OF NATIONAL INCOME, UNDER CONDITIONS OF 1920'S

according to the average levels for the 1920's and the 1930's, let us use the mid-points on the trend line, in 1926 and 1936, respectively, in calculating the average saving. The results are shown in Table D.

The data shown in Table D are charted in Figure 8. The upper portion of the chart, for the conditions of the 1920's, shows that a static equilibrium between saving and private investment, with no quasi-investment from public finances or from net foreign balances, would have been reached at a level of gross national income of about 70 billion dollars. In comparison with the 90 billion dollars of gross national income in 1929, this shows that even in the 1920's the point of static equilibrium between saving and private investment was materially lower than the full employment level, and that the higher average level of income in that decade was maintained only through the aid of

continuous quasi-investment, either public financing or net foreign balances from capital exports.

In the 1930's, on the contrary, the point of static equilibrium between saving and private investment alone was apparently lower than the smallest national income experienced in that decade. Within the income range experienced in the 1930's, the gap between saving and private investment became steadily wider as national income rose, increasing from about one billion dollars at a 50-billion income level to

3½ billions at an 80-billion income level. Under those conditions, large net public contributions to buying power helped maintain employment and income, but any time the public expenditures were withdrawn, industrial activity and income would promptly decline. So long as the propensities to save and invest in private investment remain at the levels indicated in the lower portions of Figure 8, continued large net public expenditures (or an even more marked mercantilistic foreign trade and foreign investment policy than prevailed in the 1920's) would be necessary to maintain even a modest level of national income.[26]

Under dynamic conditions. Dynamic elements are present in both the factors related to the propensity to save and in factors related to

[26] The gap between saving and private investment is not wholly determined by saving. Instead, the amount of saving is partly determined by the existence of a gap between planned saving and planned private investment. This gap can be closed either by factors operating on the investment side or on the saving side. For instance, the dissaving resulting from business losses or from the borrowing of the unemployed may be an equilibrating factor as well as unplanned variations in temporary investment and quasi-investment.

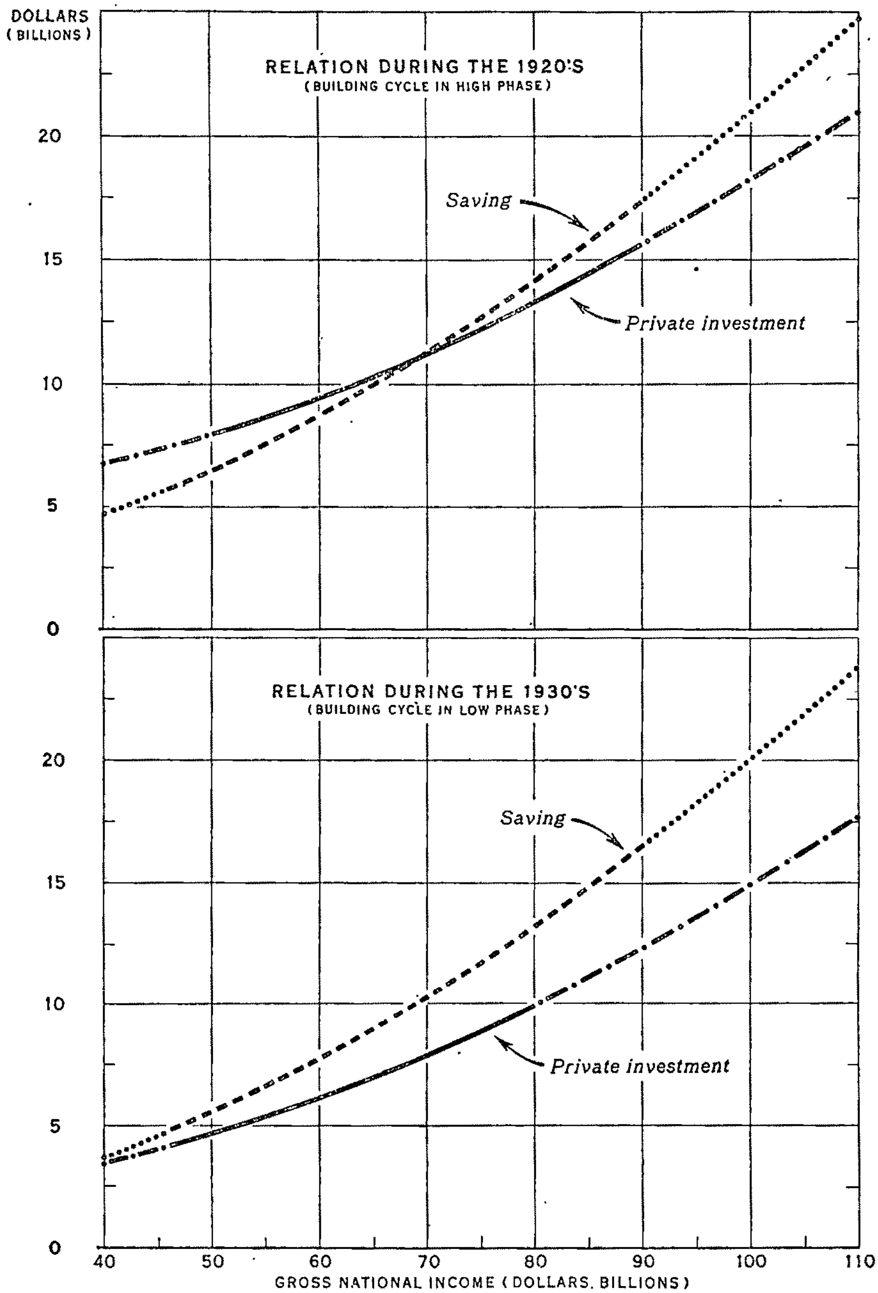

FIG. 8—Total Saving and Private Investment Expected for Given Levels of Income under Static Conditions.

the propensity to consume. On the saving side, saving rises or falls together with the extent of *change* in national income; on the investment side, temporary investment varies markedly with the changes in national income. These two dynamic elements may be compared as follows:

TABLE E—FUNCTIONAL RELATIONS OF GROSS NATIONAL INCOME TO SAVING AND PRIVATE INVESTMENT

(In billions of dollars)

Change in Gross National Income	Addition to Saving[a]	Temporary Investment[b]
−15	−3.0	−3.4
−10	−2.0	−2.1
0	0	+0.5
+5	+1.0	+2.0
+10	+2.0	+3.6

[a] From Figure 6 of Part I.
[b] From Figure 7 of this article.

These two dynamic factors tend to parallel one another.[27] This may explain why in boom periods there can be a temporary equilibrium between saving and investment at levels materially higher than could be maintained at a continuing or static equilibrium.

The dynamic relations between saving and investment can be further illustrated by comparing the two over a series of years of changing income levels, just as was done earlier for investment alone in Table C. Using the same series of changing levels of national income, the comparison is shown in Table F (see page 298).

Table F shows how widely both saving and private investment vary in a dynamic situation, and how the two tend to vary together. When the data are charted (Figure 9), this similarity of movement is again striking. As a result of the dynamic factors, private investment (under the conditions of the 1920's) could apparently about keep in balance with saving all the way up to an 85-billion dollar income on a rising level, but if income had increased above that level saving would have exceeded private investment even under dynamic conditions. Similarly,

[27] The differences between the two columns of Table E are of doubtful statistical significance. They reflect in part the fact that a straight line was used in fitting the regression to $X_{2_{(1-0)}}$ in Figure 6 of Part I, whereas a curve was used in Figure 7. Also, the 1934 observation was excluded in the latter consideration, and not in the former. There is the possibility that both columns of Table E represent merely two measurements of the same thing—first viewed as saving, and then as investment. More detailed analyses, using quarterly or monthly data and determining the extent and degree of lags present, if any, would help to resolve these doubts.

as income fell below the 60-billion mark, saving would shrink to less than the current investment.

These relations suggest that, under the conditions of the 1920's, business cycles would be unable to carry income up above 85 billions, or down below 60 billions, without starting a reverse movement (if only private investment were present). This analysis of the dynamic factors in saving and investment may thus throw some light on why the turning points in business cycles have come where they did. In addition, there is some point at which the dynamic elements themselves

TABLE F—PROPENSITIES TO INVEST AND TO SAVE AT VARIOUS DYNAMIC LEVELS OF NATIONAL INCOME, UNDER CONDITIONS OF 1920'S

(In billions of dollars)

Year in Sequence	Gross National Income	Corresponding Level of Private Investment[a]	Corresponding Level of Saving[b]
1	90	—	—
2	80	10.65	12.15
3	70	8.60	9.25
4	60	6.75	6.65

will change. Once all the old inventories have been used up, or all the accumulated debts paid off, temporary investment cannot continue negative, no matter how rapidly business is still declining. This saturability of the change factors, as well as the relations mentioned above, may also be of importance in determining the timing of business cycle turns.[28]

[28] In this comparison it has been assumed that national income would change from year to year as shown in the first column of Table F. A dynamic model of the type suggested earlier would be necessary to determine what sequence of incomes would be most likely to occur under the conditions assumed. All that is shown here is the probable saving-investment relation *if* the assumed sequence *did* occur.

C. *Investment under Stable Economic Conditions*

Probable Investment

The relations of investment and income which have been described to this point are those which occurred during a period of continuously and widely oscillating economic activity. We attempted to infer the probable investment under static conditions from the records of that period, by removing the variations associated with change. We could not be wholly successful even then. If business men generally chose to

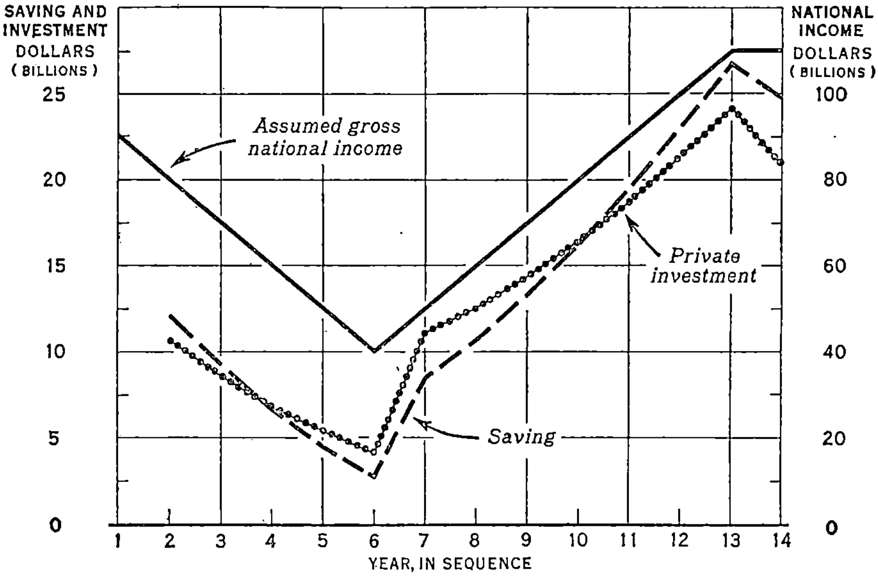

FIG. 9—Total Saving and Private Investment Expected for Given Levels of Income under Dynamic Conditions (and High Phase of Building Cycle).

under-replace depreciation when activity was low, and to over-replace when activity was high, that would still be reflected in the "static" measure of investment at high and low incomes. When we note from Table A that at 60 billion dollars income we had (in the 1920's) 4.65 billions of investment in plant and equipment, and at 90 billion dollars we had 10.45, we can see that an acceleration factor must have influenced the results. Surely it would not continuously take more than twice as much plant and equipment investment to maintain an income only 50 per cent greater.

When we look to the future, and ask what the investment-income relation would be if economic activity in the post-war world could be made more stable, we wish to estimate investment under conditions

quite different from the recurrent booms and depressions of the past. Once we are through the immediate post-war period of rebuilding and restoring the war devastation, the object of economic policy should be to maintain continuously thereafter reasonably full employment and production. That does not imply a static economy operating at unchanging levels of income, but rather a steadily progressing economy. The national income should rise steadily at the rate commensurate with both population growth and rising productivity per worker.[29]

Our analysis of investment under the widely fluctuating conditions of recent years throws little light on the question of what annual investment would be needed to sustain a steadily rising level of income. What is desired is to estimate probable investment under such more stable conditions. One approach can be made by using the average investment over the past period as a whole, rather than the year-to-year variations. From 1921 to 1940 we expanded our productive equipment from one capable of turning out about 75 billion dollars' worth of goods and services a year (in 1923) to one capable of turning out 82 billions (in 1940), in terms of current dollars.[30] If we take this average rate of progress as a reasonable estimate of probable progress during the future, we could use the ratio of average investment in plant and equipment during these two decades to average national income to estimate the normal investment required per dollar of national income. Gross expenditures for producers' plant and equipment averaged 10.2 per cent of gross national income during this twenty-year period. Assuming 110 billion dollars gross national income as the income which might represent full employment in the early post-war years,[31] this proportion indicates a probable investment of 11.2 billions as the gross plant and equipment investment needed at that income with a stably rising rate. If we assume that the housing cycle post-war will average as high as during the twenties, and extrapolate the relation shown in Figure 6, we would estimate about 5 billion dollars expenditure for housing at a 110-billion income level. (Note Table A.) Adding in the average inventory increase of 0.5 billion, and the average increase in consumers' credit of 0.3 billion, gives a total estimate of private investment (excluding foreign loans) of about 17 billion dollars a year.

The estimate based on the past two decades can be checked against

[29] Presumably real per capita income would not rise quite as fast as real productivity per hour, as some of the increased productivity would go into shorter hours and more vacations, rather than entirely into higher consumption of goods and services.

[30] Adjusting for the lower price level in the thirties, the increase in real product was much greater. In 1929 prices, the increase in productive capacities at successive peak years was from 74 billion dollars in 1923 to 90 billions in 1929, and to 97 billions in 1940.

[31] This assumes a post-war reduction in price level to about the 1935-39 average.

TABLE IV—NATIONAL INCOME, CAPITAL FORMATION, POPULATION GROWTH, AND INCREASE IN PRODUCTIVITY, 1879–1938

Period	Average Real Gross National Product, Per Consuming Unit[a]	Change in Product from Previous Period[b] X_3	Population Increase During the Decade[c] X_2	Gross Capital Formation in per cent of Gross National Product[d] X_1
	dollars	per cent	per cent	per cent

the investment record over a more extended period. Kuznets's study of capital formation since 1879[32] supplies a record of capital formation and gross national product over six decades. These data provide a series of observations of the average investment required to sustain various average levels of national income under varying rates of progress, over periods long enough in each case so that the short-time acceleration and deceleration of investment due to business cycle changes has in large part been eliminated.[33] These long-period averages, shown in Table IV, are far more stable than the yearly data. The decade averages vary between 14.6 per cent and 21.2 per cent of gross national income, whereas Kuznets's corresponding annual estimates of gross capital formation (1919-35) varied between 28.1 per cent and 6.6 per

[32] Simon Kuznets, "Capital Formation, Past and Present." (Paper presented at the meeting of the American Statistical Association, held in New York, December 29, 1941.)

[33] Average investment over low and high periods may exceed that required under stably rising conditions due to unwise and wasted investment encouraged under boom conditions. There is little present basis for judging how much of an overestimate of required investment this would be likely to produce.

cent during the 1920's and 1930's.[34] Our estimate of 17 billions private investment at 110-billion national income, or 15.5 per cent of gross national income, falls near the bottom of the range shown by Kusnets's decade averages.

The proportion of gross national income devoted to gross capital formation varied considerably during different decades. In general it was highest in decades in which the population was growing most rapidly, and in which the real product per capita was expanding most rapidly. (The data for these factors also are given in Table IV). After experimentation with these and other factors, it was found that over eight-tenths of the variation in the per cent devoted to capital formation from period to period could be explained by these two factors.[35] From this relation, based on American experience over a long term of years, it is possible to make at least a rough estimate of the requirements for capital formation under future conditions, assuming various future rates of population growth and technological progress.

The estimates of population growth between 1945 and 1954 indicate a prospective population increase of 5.1 per cent during the decade.[36] If we assume that technological progress will continue in the future at the average rate it has during the past, that would give a value for

[34] Simon Kuznets, *National Income and Capital Formation, 1919-35* (New York, Nat. Bur. Econ. Research, 1937) pp. 8, 40. His annual figures on gross capital formation are used for this comparison instead of the figures of offsets to saving shown in Tables 1 to 3. Kuznets' classification differs in some respects from these investment items.

[35] In this analysis, the multiple regression equation determined was:

$X_1 = 14.093 + 0.288X_2 + .171X_3$

where

$X_1 =$ gross capital formation, for each decade, in per cent of gross national income (in current dollars)

$X_2 =$ per cent increase in population during the decade, from the middle of the first year to the middle of the tenth

$X_3 =$ per cent increase in real gross national product per capita, in the given decade over the average for the preceding period (half overlapping), as shown in Table 4.

The multiple correlation was $\overline{R}^2_{1.23} = 0.84$, and the standard error of estimate $\overline{S}_{1.23} = 0.9$. The fact that the individual observations represented decades half overlapping reduces slighty the significance of these results, as the successive observations were not completely independent. In effect, however, these 11 overlapping periods contain the record of what happened during the 12 periods of 5 years each which compose them, so there is not much exaggeration of the number of degrees of freedom involved in the analysis.

Other measures might have been employed in stating X_3, such as determining the average annual growth of real product by fitting a trend line to each 10-year period separately. This cannot be done until the income estimates are available for individual years. It is not believed, however, that the use of such refinements would change the conclusions materially.

The size of the constant in the regression equation, 14, indicates 14 per cent of the national product would be required for gross capital formation even with no change in population or productivity. This compares with about 11 per cent for depletion and depreciation estimated by Kuznets.

[36] *Population: Estimated Future Population, by Age and Sex, 1945-1980. The United States*, Series P-3, No. 15 (Washington: U. S. Dept. of Commerce, Bur. of the Census, July 23, 1941.)

X_3 of 6.8 per cent. (Since this measures the average increase in real per capita production from one 10-year period to another 10-year period beginning at the middle year of the first, or 5 years later, it is equivalent to an increase of 1.3 per cent per year. This is somewhat smaller than the long-time rate of growth in output per capita found by Carl Snyder,[37] just over 2 per cent per year.) At these rates of growth in population and in productivity, the previous experience indicates that gross capital formation of 16.7 per cent of gross national income would be required. For a level of 110-billion dollar national income, this would mean a gross capital formation of 18⅓-billions, somewhat more than the private investment of 17 billions estimated by the previous simpler method.[38]

Either of these estimates of probable investment differs materially from the estimate which could be derived from Table A. That table gives 20.5 billions as the probable investment at 110-billion income under static conditions, with the higher phase of the housing cycle. Adding on the 0.8 billions for average annual growth in consumers' credit and inventories brings it up to 21.3 billions, or considerably above the comparable estimates of 17 billions based on the average relation for the 1920's, or of 18⅓ billions based on the longer series, with an assumed somewhat higher average rate of technological expansion. It is quite clear that, if we were to apply the relation of income and investment observed under widely varying levels of income to estimate the amounts which could be privately invested under more stable but high levels of income, we would materially overestimate the probable amount.

Saving versus Investment under Stable Economic Conditions

The previous calculations may now be brought together to determine the probable gap between saving and private investment under stable conditions of full employment, on the assumption that the other institutional factors (distribution of income, tax rates, etc.) do not differ materially from those which prevailed during the past two decades.

Our previous assumptions as to a steadily rising rate of national income are equivalent[39] to an annual increase of 1.9 per cent in national income (at constant prices) which would mean an increase of 2.1 bil-

[37] Carl Snyder, *Capitalism the Creator* (New York, Macmillan, 1940), p. 415.

[38] Gross capital formation, as defined by Kuznets, differs slightly from gross private investment as calculated here. The former includes capital formation by public agencies and by export investment, but excludes all consumers' capital formation except housing. The latter excludes the first two items, but includes consumers' capital financed through net increases in consumers' credit.

[39] Population was assumed to grow at an average rate of 0.6 per cent a year, and real per capita production to rise at an average annual rate of 1.3 per cent. Real national income then must rise at an annual rate of 100.6×101.3, or 1.9 per cent.

lions upon reaching a 110-billion level. From the relations shown in Figure 6 of the preceding article, we estimate probable saving (say for 1945) with gross income at a 110-billion level, increasing at 2.1 billions per year, at about 23.5 to 25.5 billions of dollars.[40] This compares with a probable level of private investment, just calculated, of about 17 to 18 billions of dollars, leaving a possible gap somewhere between 5.5 and 8.5 billions of dollars.[41] Unless changes in tax structure, in industrial wage and price policy, or in other related factors, change the habits of saving or of private investment significantly from those which prevailed prior to the war, it appears that after the war average annual expenditures of about 5.5 to 8.5 billions of dollars, in public offsets to saving or in foreign investment, would be required to keep the economy running at full employment and with a steadily rising level, at the time that gross national income was crossing the 110-billion level.[42] To the extent that changes in consumption habits, tax structure, or business policies and income distribution should lower the amount of saving made at given income levels, or force an increase in the amount of investment above that hitherto required at the same income level, the average public expenditures necessary to maintain full employment would be reduced.

D. *Suggestions for Further Study*

The studies of saving and investment reported in this and the preceding paper constitute only a reconnaissance study of a very broad

[40] Assuming the trend of saving by 1945 to be at the average level shown in the lower section of Figure 6 in Part I of this article (which means refusing to extrapolate the rising trend into the future in the absence of more positive confirmation of this shift), and calculating the amount for an income of 110 billions and an annual increase of 2.1 billions, gives 25.6 as the actual estimate. (Of this 25 billions is the reading from the upper line of Figure 6 and 0.6 billion is read from the middle line, for the change in national income.) If the upper curve of Figure 6 had been extrapolated as a straight line instead of a curve, however, the estimate would have been about 23.6. In view of the considerable margin of possible error which attaches to estimates from any such extrapolation of a regression line beyond the data on which it is based, it is felt safer to give the estimate in terms of the range shown above. (For the reliability of such extrapolations, see the present author's text, *Methods of Correlation Analysis*, pp. 347-49.)

[41] In boom periods in the past, profits and upper-bracket incomes have increased out of proportion to wages and salaries. The estimated increases in saving assume that this same disproportion would prevail at high levels of national income in the future. Under conditions of high but stable production, as assumed above, it is quite probable that income would not be quite as unequally distributed as this assumes, even without any conscious modification in business price and profit policies. If that should prove to be the case, the level of saving and the size of the gap would be somewhat smaller than estimated here.

[42] This differs materially from the probable size of the gap in the years immediately after the war. Foreign rehabilitation and domestic replenishment of wartime depletion of both producers' and consumers' capital might temporarily raise investment to levels which would close the gap entirely or even threaten inflation. These estimates indicate the possible magnitude of the problem of maintaining employment after the boom of that post-war restocking is completed.

group of problems. In this preliminary exploration many problems have been encountered which it has been necessary to pass by or to subject to only superficial examination. They call for careful and exhaustive analysis, both theoretical and quantitative, before the basic relations can be fully determined. The control of business cycles and the prevention of periodic deep and sustained depressions have been among the most puzzling of all economic problems. Research in this field is important at this time as a background for post-war economic policy.

Some of the more important quantitative studies which remain to be undertaken in the field of saving and investment are:

1. Determination of the size, and study of the behavior, of separate components of savings, particularly of individual and business savings, in relation to national income.
2. Further study of the influence of financial institutions, such as commercial banks, investment trusts, and life insurance companies, upon both saving and investment.
3. Study of the distribution of income as a factor affecting saving and consumption. This requires extension of consumer expenditure studies, particularly with the purpose of determining what actually happens to expenditures when people shift from one income level to another. In addition, attempts should be made to determine what consumer expenditures and saving patterns would be under different distributions of income, assuming stable levels of income or progressively rising levels of income in response to increases in population and to rising productivity per worker.
4. Determination from the standpoint of the foregoing study of a distribution of income which would so modify the consumption and saving habits of individuals that outlets in useful investment could easily be found for the saving which would be done.
5. Studies of the probable effects of particular institutional changes upon consumption and saving habits. This includes among others consideration of the probable effects of specific changes in price, wage, and profit policies; in social security provisions; and in tax structure.
6. Analysis of factors influencing investment decisions in individual industries, including determination of the relation between investment in plant and equipment, and profits, use of capacity, and other internal and external factors.
7. Further development of a stable relation between investment and income with a steadily but gradually rising level of income rather than a widely fluctuating level, as tentatively developed in Section C of the present article.
8. Further study of the apparent private investment-income relation, developed from data for the past two decades (Figures 5 and 6 of this

article). In this connection a breakdown of investment expenditures into those for replacement and those for new investment, already suggested, would be useful.

A great many research studies dealing with various phases of the problems developed here are now being planned in connection with the work of several federal agencies in the field of post-war planning. Future students will need to develop more clearly the general relationships explored here. We must create a continuously more solid and factual basis for this important sector of economic knowledge.

E. *Conclusions*

The results of this general survey of the existing American data, in the present article and the preceding one (Part I), may now be formulated in terms of the hypotheses with which the study began. The results support the validity of the following propositions:

1. The quantity of current income withheld from consumption expenditure (saving) is functionally related both to the current level of income and to the direction and extent of change of that level, increasing as the level of income and production increases.

2. The quantity of current income spent privately for permanent capital goods under conditions of fluctuating activity has responded to previous profits, but has been conditioned by the *current level* of income, while the income spent for temporary private investment has been related to the direction and extent of *change of the level* of income (and hence to the anticipations of future returns which may be associated with those income levels and changes). No evidence could be found that reductions in interest rates stimulated investment during the period studied.

3. The phase of the housing cycle is a major factor related to the amount of investment and is at least a minor factor related to the level of the saving function. The relation of saving to private investment was materially different in the 1920's than in the 1930's, primarily due to the differences in the phase of the housing cycle.

4. Because of the functional relation of the rate of change in income to both saving and investment, the static relation of the two is different from the dynamic relation.

5. As between different static levels of national income, under the conditions of the 1920's, the increase in saving associated with a higher level of national income was larger than the increase in private investment, and the point at which the two were in static equilibrium was far below full production or full employment. Under the conditions of the 1930's, saving was higher than private investment at all levels of national income experienced, and large net additions from public expendi-

tures and foreign balances were necessary to attain an equilibrium, with the size of the gap increasing with the level of national income. Even in the 1920's, material quasi-investments were necessary to maintain the levels of income then realized.

6. With changing levels of income, both saving and private investment ran relatively large on the way up, and relatively small on the way down, with private investment tending to fall below saving as soon as the rise in income passed about 85 billions on the way up, and to remain below until national income fell to about 60 billions on the way down (under conditions of the 1920's).

7. With employment maintained at a high level, and national income rising at a steady rate, the gap between saving and investment would probably be much larger than it has been in past peacetime periods of high but transitory full employment. To maintain stable full employment in the post-war period, saving will have to be reduced or investment supplemented, to an extent averaging 5½ to 8½ billions a year, if full employment is to be maintained at a steadily rising rate around 110 billions of income.

Washington, D.C.

THE INFLATIONARY GAP

I. Meaning and Significance for Policy Making[1]

By Walter S. Salant

In economics, as in ladies' fashions, the war has created a new vogue—the "inflationary gap." Its measurement is the latest and perhaps one of the most popular of the increasing applications of statistics to questions of national economic policy. Since the phrase is now breaking into the newspapers economists are obliged, if only in self-defense, to have a clear understanding of it.

The currency of the phrase is, of course, a reflection of the enormous wartime increase in government spending and the resulting danger of serious inflation. Although the phrase is new, the idea that it represents is familiar; namely, the excess of demand over supply at a specified price, applied to total effective demand, aggregate supply, and some price level. The concept is most often used in connection with tax policy, specifically in calculations of what amounts of additional taxation are required to prevent inflation.

Instead of considering first the meaning or rather the various meanings of the term "inflationary gap" and then considering estimating procedures, it may be more instructive to reverse the order and to consider two estimating procedures first and then to compare their meanings.

All procedures involve a comparison of estimates of the potential real output of goods and services with estimated demand, based upon assumed levels of defense expenditures. In most cases some recent date is taken as a base. It is assumed that the prices of this base date are the ones to be stabilized and therefore that the gap at that date is zero. Consequently, the various supply and demand factors are expressed in terms of changes from that base.

1. The procedure used in a report soon to be published[2] compares the expansion of real output with the increase in defense expenditures (supposedly on the basis of deliveries of defense material) and obtains as a difference the necessary reduction of civilian output. It then estimates the independent change in demand for civilian output that will

[1] A paper presented in New York City on December 29, 1941, to the Econometric Society at its annual meeting.

[2] A report on the amount of taxes needed to avert inflation prepared by Carl Shoup, Milton Friedman, and Ruth Mack for the Carnegie Foundation and the Institute of Public Administration. Since the report has not yet been made public, I am deliberately refraining from describing the estimating procedure in detail and also from appraising it.

occur if no new anti-inflationary measures are adopted. This is done by considering the changes in each component of capital formation (*i.e.*, residential construction, inventory accumulation, plant and equipment expenditure, etc.) and the change in the propensity to consume separately. In order to estimate the autonomous changes in the propensity to consume and in private capital formation it is, of course, necessary to work on certain hypotheses with regard to the distribution of income, the movement of prices, and so on. As a first approximation the independent changes in the propensity to consume and in capital formation are estimated on the assumption that prices and disposable income of consumers are the same as on the base date. In estimating these changes an attempt is made to take into account the effects on demand of direct controls such as priorities and allocations and all other relevant factors. The estimated changes in the propensity to consume and in capital formation are then added to give the total estimated change in private demand for civilian goods.[3] This change in demand is then compared with the necessary change in civilian output. The difference is the amount of reduction in civilian demand that must be brought about by new measures of policy.

If it is found that defense spending will increase by 15 and physical output will increase by 8, civilian output will have to decrease by 7. If it is found further that civilian demand at the disposable income of the base date will, independently of any new policy measure, increase by 2, then steps must be taken not only to prevent this increase of demand but actually to reduce demand by 7. In other words, a total reduction of demand by 7 + 2 or 9 is required. This figure, representing the amount of reduction in civilian demand that must be brought about by special measures, is the inflationary gap according to one definition.

In computing the severity of the measures required to eliminate this gap, it is of course necessary to take into account their secondary effects. It is also necessary to consider what steps are required to fulfill the assumption on which the estimates of change in demand were based. Since the gap was computed on the assumption that disposable consumer income remained unchanged, a gap of zero would still require new measures to be taken. It would still be necessary to keep disposable consumer income the same as it was on the base date, and this would require some kind of action. Thus the quantitative amount of special measures needed would differ from the gap itself on this definition of the gap.

[3] To be strictly correct each of these two components of civilian demand should be reapproximated to take into account the estimated change in the other component. The authors of the report found this to be unnecessary in practice.

This definition of the gap measures the amount by which investment plus the propensity to consume at base date prices and base date disposable consumer incomes exceeds the investment and the propensity to consume which would be consistent with equilibrium of demand and supply. This gap does not measure the increase of investment and total consumption that would occur if no measures were taken to preserve equilibrium, for if no measures were taken the excessive investment and consumption would have secondary effects which would further increase demand. These secondary effects are not measured. This procedure tries to avoid dealing with the functional relationships which would be needed to estimate these secondary effects. For example, it does not deal with the curves of the propensity to consume. It deals with those points on the curves that correspond to the consumer disposable income of the base period. In other words, this method does not measure what would happen if equilibrium is not preserved. It simply estimates the conditions for equilibrium.

2. A second method, developed in the Office of Price Administration, attempts to work with a logically complete system of interdependent quantitative relations representing the demand for goods. In using these relations, however, an attempt is made to take into account new factors that modify them, such as priorities, allocations, rationing, inventory control, etc. Beginning with independent estimates of government expenditures and exports and using certain multiplier relations, the total expansion of national income is worked out. The estimates of government expenditure are, however, first analyzed to see what quantity of various durable goods production they imply. These estimates are in turn compared with the capacity for producing the more important durable goods in order to estimate the limitations that will have to be placed on civilian durable goods expenditure by the allocation authorities. In solving the system, the demand for these goods is not permitted to rise above these limits.

This restriction is an explicit recognition of a point often neglected in discussion of inflation: that allocations and price control limit not only the quantity of scarce goods that can be bought but also the demand for them. If firms cannot get materials required for capital expenditures they will not bid for them and the expenditures will not be made. Furthermore, if a business cannot make a capital expenditure, it is unlikely to divert the funds to any other purpose that will result in new spending and therefore no offsetting increase in demand is likely to occur. In the case of scarce consumer durable goods some diversion of expenditure is likely to occur. Allowance is made for this in the calculations: Total consumer demand is reduced by less than the reduction in demand for the scarce consumer commodities.

The solution of the system gives, simultaneously, *total* effective demand for all goods, net corporate saving, various types of tax receipts, consumer disposable income, consumer expenditure, etc.

These results are then compared with the practically attainable national product measured in the prices at which stabilization is desired. The excess of the calculated total effective demand over this practically attainable total supply represents an inflationary gap, which may be called the *total income gap*. The excess of consumer expenditure over the consumer expenditure that could be satisfied at the desired price level, which can also be obtained by this procedure, represents another inflationary gap which may be called the *consumer expenditure gap*. The calculated consumer expenditure implies a calculated consumer income after taxes. The level of consumer expenditure that can be satisfied at the desired prices of consumers' goods also implies a certain level of consumer income after taxes. The difference between this calculated and the equilibrium consumer incomes after taxes represents another inflationary gap, which may be called the *disposable consumer income gap*. There are still more inflationary gaps that could be enumerated, but further enumeration would add nothing.

All the gaps that emerge from this second procedure differ from the gap obtained in the Shoup-Friedman-Mack procedure in being total gaps; that is, they are the excess of total income (or of consumer expenditure or of disposable consumer income) after allowance is made for the secondary spending. The reduction of investment which is required to eliminate these gaps is a fraction of them. The Shoup-Friedman-Mack gap, on the other hand, might be called a primary or a saving-investment gap. It does not take account of secondary spending that would take place if it is not eliminated. It will always be less than the total income gap unless there are no secondary effects.

Still another gap is the tax gap, or the amount of taxes that would have to be raised to eliminate the gap. Within this category there are two cross-classifications.

(a) The amount of taxes required to eliminate one gap is not necessarily the same as the amount required to eliminate another. For example, the consumer expenditure gap might be eliminated by one amount of taxation while a higher amount might be required to eliminate the total expenditure gap. In other words, there are several tax gaps depending upon what excessive demand one wishes to eliminate.

(b) The amount of additional revenue required to achieve any given reduction of demand depends on the nature of the new taxation. New revenues of 2 billion dollars raised by a sales tax may be equivalent to additional revenues of 4 billion dollars raised primarily from corpora-

tions and individuals with high incomes, so far as their effect in reducing consumption is concerned. For this reason there are any number of tax gaps corresponding to each desired reduction of demand.

The relation between the many concepts of the gap can best be shown by setting up a system in which all the relevant factors are included explicitly, but I shall not here introduce a set of equations for that purpose. It is sufficient to emphasize that there are many variations of the inflationary gap and that a mere statement that some expert estimates the inflationary gap at so-and-so many billion dollars means nothing unless he specifies what concept he is using. Even that would be hard to specify until there is some standard terminology for the different variations. It will usually be necessary to examine the statistical procedure to find out for oneself. Without such an examination both agreements and serious disagreements as to the prospects for inflation may be concealed. Two experts may come out with the same figure yet one may be estimating the primary gap and the other the total gap. The former estimate may actually imply a pressure of demand two or three times the magnitude of the latter, but without examination the two will appear to agree. Let me say that this is not merely a theoretical possibility.

Analyses of the gap type appear to assume that there is a unique supply curve for output as a whole, at least with any given composition of total demand. This follows from the implication that, with given physical productive capacities, rising prices can be prevented only by restricting demand. The problem is usually stated in terms of what amount of demand is consistent with maintenance of base date prices. The answer is usually found by comparing demand with the physical potential valued at those prices. When the problem is stated and answered in this way, there is an implication that the supply curve is not only unique but is infinitely elastic at the base date prices up to the point where this potential output is produced.

To avoid such an extreme implication, a more careful statement is required. The question might be asked in this way: What increase of demand is compatible with an increase of prices not exceeding a certain desired percentage? The answer would then be found by solving for the increase which made demand equal the supply that could be produced at this maximum desired price level. If output is not infinitely elastic up to full capacity, this supply which determines the maximum permissible demand is lower than that which the economy is physically capable of producing. In other words, before the gap can be measured it is necessary to decide what expansion of output is attainable with what price increase and it is further necessary to decide what com-

promise is to be made between rising prices on the one hand and sacrifice of production on the other.

It may be argued that no sacrifice either of price stability or of output is necessary, that demand should be permitted to rise to the maximum possible output, measured in base date prices, and that those prices can be maintained by direct price controls. If price controls are necessary before maximum output is attained, the supply curve must have a finite elasticity, and if it is a unique supply curve the maintenance of base date prices by direct controls would inhibit output. It follows, therefore, that those who believe both that direct price controls are necessary and that they will not prevent the attainment of maximum output do not believe that there is a unique supply curve.

Let us turn now to the policy implications of gap analysis. It is usually applied in connection with tax policy in order to determine the desirable amount of additional taxation. Even if one accepts the assumption that price stability should be sought by restraining the growth of demand, one may measure the inflationary gap without getting any guidance whatever as to how far demand ought to be restrained by taxation. It must be remembered that increased taxation is only one of several methods of affecting demand. Its effects are distributed fairly generally over the objects of expenditures and it can be focused on particular types of goods only to a limited extent. The gap, on the other hand, does not necessarily imply a general excess of demand. The fact that it is usually derived and expressed in terms of global income and expenditure figures makes it easy to forget this fact. The gap is a summary expression reflecting a total of many separate excesses of demand over supply at the desired prices for many different commodities.

For the determination of policy it makes all the difference in the world how these separate excesses are distributed. If demand is generally excessive in terms of potential output at the desired prices for all types of goods, durable and nondurable, producers' and consumers', general measures of the income tax variety are appropriate. If the total gap is composed only of excessive demand in the durable goods field, however, and not at all in the field of nondurable consumers' goods, measures that affect primarily the demand for the latter are not particularly helpful.

The basic economic fact here is that resources are not perfectly fluid. If the output and the productive resources that satisfy consumers' demand for nondurable goods cannot be used to satisfy the excessive demand, as is the case with regard to the matériel component of defense expenditures, then no purpose is served by restricting demand for the

goods that are not scarce. Where this is the case it is far more appropriate to use measures that restrict demand for particular services, for example, allocation and rationing.

If the expert tells the policy maker only the amount of the total gap, he is not giving sufficient assistance in the formulation of policy. The very least that the policy maker ought to require of the expert is an estimate of the composition of the gap as between broad classes of output. For this purpose output should be classified according to the resources required in production. Theoretically, goods that require the same sort of resources should be in one class; other goods that cannot be produced with those resources should be in different classes. In practice some part of the resources required to make one product will almost invariably be of some use in producing some other, so no detailed classification can be perfect in practice. But a grouping into durable and nondurable goods is extremely useful. The gaps in each group should be estimated separately. Then the policy maker has some guidance as to what sectors of the economy his policies should be designed to hit. The measurement of the excess of total demand over the level desired is only a first step or a summary expression. If no breakdown of total demands and supplies is provided, the gap is merely a summary measure of the aggregate inflationary pressure. If the existence of a *total* gap is carelessly assumed to imply the existence of a *general* gap, the concept may be more dangerous than helpful.

Office of Price Administration
Washington, D.C.

II. Discussion of the Inflationary Gap[4]

By Milton Friedman

Driving along the beautiful Skyline Drive in Virginia recently, we passed Lands Run Gap, and then Compton Gap. A bit later another sign came into view. I expected it to read Inflationary Gap, but it was only Jenkins Gap. Again and again I was disappointed. Inflationary Gap never appeared. And this was entirely appropriate: Inflationary Gap is never of the past or the present; it is always in the future.

The inflationary gap is one of those *ex ante* concepts with which recent theory has made us all familiar. Double entry books always

[4] At the request of the editor, Mr. Friedman has contributed this discussion of the subject matter of Mr. Salant's paper.

balance, aside from numerical errors. Expenditures by consumers must always equal receipts of sellers. But expected expenditures by consumers during some future period need not equal the value at some specified price level of commodities and services that will be available for sale. It is this difference between expected expenditures and the value of goods expected to be available that constitutes the inflationary gap—at least, in one of its variants.

When the future has become the past, the books will still balance; expenditures will equal receipts; and the inflationary gap for that period will be no more. How does the gap between expected expenditures and expected value of goods available work itself out? How does it lead to the particular level of expenditures and receipts that is realized? Speaking loosely, how is the gap closed?

The adjective "inflationary" implies one method whereby the gap may be closed; namely, through a price rise. But this implication is in many ways misleading. The mere revaluation of the goods available for sale does not by itself close the gap; it is the redistribution of income and the change in spending-saving habits accompanying a price rise that closes the gap. And a price rise is not the only way in which the gap may be closed.

Suppose that, at some specified price level, the value of resources (including, of course, enterprise) expected to be employed in the forthcoming period is \$100; that half of these are expected to be utilized, directly or indirectly, by government in producing goods that will not be available for sale, and the other half by industries producing consumer goods; that no consumer goods are available for purchase except from current production; that there are no taxes; and that all payments for resources constitute individual income (*i.e.*, in the terminology of national income, that there are no "business savings"). Under these assumptions, the aggregate income of individuals would be \$100, and the aggegate value of goods available for purchase (at the assumed price level) would be \$50. Suppose, further, that at the assumed price level and with an income of \$100, individuals would *want* to spend \$70 on consumer goods. The inflationary gap—or that variant of it designated by Mr. Salant as the primary consumer expenditure gap—would be \$20.

With \$70 trying to buy goods, and \$50 worth of goods available, at the assumed price level, it may seem that a 40 per cent price rise would close the gap by making the aggregate value of the goods equal to \$70. But if this were to happen, aggregate income would no longer be \$100. If, for the moment, we assume other things unchanged, government would be spending \$50, consumers would be spending \$70, and

aggregate income would be \$120. The increase in the price of consumer goods means an increase in payments to some resources and, hence, in their price. If government, to compete, should have to raise the price paid to comparable resources, total income would rise even more—at this stage, to \$140. But with a higher price level and a higher income, consumers will want to spend more than \$70. Indeed, if the aggregate spending-saving pattern were unchanged, they would want to spend 70 per cent of their unchanged real income, or \$98. At the new, higher price level, then, there is a gap of \$28, replacing the initial gap of \$20. In short, if consumers were to insist on spending 70 per cent of income, and government were to insist on employing half the resources, the immovable object would be meeting the irresistible force.

The answer to this dilemma is, of course, that a price change does not involve merely a revaluation of goods and of incomes. Because of frictions and lags, price changes lead to a redistribution of incomes and to a change in spending-saving relationships. The initial increase in income from a price rise is likely to be concentrated in the hands of recipients of profits, a group that tends to receive fluctuating incomes and accordingly to save a disproportionately large part of any increase in income. Moreover, the receipt and spending of incomes are not simultaneous. All along the line, it takes time for recipients of higher incomes to readjust their spending patterns. Finally, competitive readjustments of resource prices take time. While employing, in some sense, half the real resources, government may not disburse half the money income. Under conditions like the present, of course, this last adjustment is likely to be concealed. The initiating impulse is arising from the government, not the private, sector. Government, in bidding away resources from the private sector, is raising the prices of resources. The share of money income it is disbursing may well be larger than the share of resources it is employing.[5] The point is that the secondary changes in the private sector make this difference less than it would otherwise be.

A price rise will close the gap, therefore, by changing the ratio of saving to spending and by changing the ratio of the value of goods available for sale to the total value of goods produced. At the end of the period, the balanced books will show a percentage of income saved exactly equal to the percentage of income disbursed in the production of goods not available for sale. In our simplified example, if we assume that government throughout disburses half the income, the balanced books will show that individuals have saved half their income.

[5] These are inexact statements, touching on the extremely troublesome problem of defining the volume of real resources in other than monetary terms.

How large a price rise will be required depends on the speed with which readjustments take place. If, for example, labor is quick in demanding and successful in obtaining higher wages when profits rise, and consumers are quick in interpreting rising prices as a forerunner of further price rises and hence in increasing their expenditures, a very large price rise may be required, and conversely. The same primary gap may, therefore, be associated with a wide range of price changes.

Even in the absence of direct government intervention, a price rise and the attendant redistribution of income is not the only way in which the gap might be closed. For example, to take a highly unreal extreme, sellers of consumers' goods might simply refuse to raise prices despite the high level of demand, permitting, instead, their shelves to empty and bare-shelves rationing to replace price rationing. Consumers would then be forced to save $20 more than they wanted to. This type of behavior by sellers would, in practice, be rare; but to whatever extent it occurred it would help to close the gap.

Again, aside from the increase in savings as a result of the redistribution of income, savings might increase because of a "buyers' strike" —unable to obtain the desired goods at accustomed prices, buyers might simply refuse to purchase at higher prices. This type of behavior is contrary to experience, which reveals a higher percentage of income spent on consumption goods, the lower the real income. But it is not entirely inconceivable under wartime conditions and psychology.

Finally, the gap might be closed by changes arbitrarily ruled out in our simplified example. As Mr. Salant quite properly points out, aggregate output—at least "economic" output—is not unique. A price rise might mean a larger output than the $100 assumed in our example, and hence more goods available for sale. And goods can be made available for sale not only from current production but also from capital. Such an increase in goods sold does not increase *incomes;* it merely substitutes one form of asset for another—money for goods.

Under these conditions, it may well be asked what significance can be attached to the number describing the primary expenditure gap— in our example, $20. The primary expenditure gap—the concept most frequently used in measurements of *the* gap—is significant in only two ways: (1) It measures the amount by which the estimate of voluntary savings at the assumed income level would have to be in error in order that the gap should be the product of statistical error rather than of economic reality. If the statistician had underestimated voluntary saving by $20, there would in reality be no gap. (2) It measures the task of one of the many public policies that might be used to close the gap; namely, a campaign to stimulate "voluntary" savings. In terms of our

example, such a policy, in order to succeed, would have to induce consumers with an income of $100 to save $20 more than they would want to save in the absence of such a campaign.

The $20 that measures the primary expenditure gap does not, as is often mistakenly supposed, measure the amount that would have to be raised in taxes to close the gap. If, in our example, $20 were withdrawn in taxes, consumers would have available $80 for saving and spending—at the assumed price level. Out of $80 of income, they would presumably want to spend less than $70 but more than $50, since a reduction in income ordinarily reduces both saving and spending. In order to eliminate the gap, enough would have to be withdrawn in taxes to reduce disposable income to a level at which consumers would want to spend $50. This would clearly require more than $20, how much more depending not only on saving-spending habits but also, as Mr. Salant has pointed out, on the kinds of taxes imposed.

An analysis directed toward policy should not, therefore, stop with an estimate of the primary expenditure gap. It should take as its function the evaluation of the quantitative aspects of the alternative measures that might be taken to close the gap. Such an evaluation is essential to an intelligent choice among measures or an intelligent combination of measures. It is not enough to list the various measures that might be taken: direct stimulation of savings; reduction of consumer income through taxation or compulsory savings; indirect stimulation of savings by rationing some goods and thereby narrowing the range of goods freely available for purchase, or by imposing restrictions on consumer credit; rationing of over-all purchasing power; reduction of expenditures by industry on non-war capital formation, and by state, local, and federal governments on non-war activities; prevention of wage rises; elimination of overtime payments; etc. There is needed, in addition, quantitative estimates of the contribution that would be made by each possible variant of each measure, and by combinations of different measures. The ideal would be a series of indifference surfaces, so to speak; *i.e.*, a list of the alternative combinations of policies that would serve to close gaps, however defined, of alternative sizes.

The analyses that have so far been made fall far short of this ideal. In the main they have been directed at measuring either the primary expenditure gap—the measure appropriate for a policy of direct stimulation of savings; or the tax gap—the measure appropriate for a policy of reducing consumers' disposable incomes through taxation. True, these studies have attempted to take into account the effect of other policies, in so far as these policies could be foreseen. But only to a minor extent have they attempted to state the consequences of extensions of the other policies—to say, for example, that this and this ex-

tension of rationing would change the amount of taxes needed by this and this amount.

Mr. Salant stresses the importance of a somewhat different elaboration of the estimates—a breakdown of the gap among broad classes of output. He considers such a breakdown vital for policy purposes because, in his view, "general measures of the income tax variety are appropriate" primarily "if demand is generally excessive in terms of potential output at the desired prices." This apparently innocent statement conceals a joker—"at the desired prices." The composition of the gap is determinate only at specified relative prices for different classes of goods.[6] It can be anything at all if relative prices are permitted to vary. Mr. Salant's policy conclusion is valid only if (1) stabilization of particular prices as well as of the general level of prices is desired, or (2) relative prices are generally and necessarily rigid. Neither point seems to me to be acceptable. General measures of the income tax variety seem appropriate under almost any circumstances—certainly any that are at all probable in the United States. The price system seems the least undesirable method of allocating the limited resources that will be available for the production of civilian goods. If they could be constructed, breakdowns of the type suggested by Mr. Salant would be desirable under alternative relative prices, not for determining basic policy, but rather for estimating the relative price changes that would be likely to occur.

The present state of gap analysis is unsatisfactory not only because it does not go far enough, but also because the estimates that are made are subject to such wide margins of error. At the present stage of our knowledge of the functioning of the economic system, estimating the gap is a presumptuous undertaking. One of the main by-products of attempting to do so is a keener realization of how little we know about the quantitative interrelationships of the economic system, and how much there is to know. To estimate the gap, and the consequences that will flow from it, requires precise and quantitative knowledge of the process of economic change—of how impulses are transmitted throughout the economic system, of lags in adjustment, technical possibilities, and human reactions.

Useful estimates are possible at all only because of the special circumstances of the moment. The necessities of war require an ever-increasing stream of expenditures whose desirability is unquestioned. These expenditures constitute the dominant factor making for expan-

[6] It should be noted that the aggregate amount consumers will want to spend out of a given income may also be affected by the relative prices of different classes of goods even if the general level of prices is, in some sense, fixed. But this effect would presumably be of secondary importance.

sion of money incomes. The direction of the change in expenditures is known: so long as war continues, expenditures will increase and not diminish. The magnitude of the change can be forecast with reasonable accuracy for short periods. Many factors that would be important to the estimator in ordinary times have no independent influence in wartime. For example, non-war capital formation is subject to direct control and is determined by availability of materials rather than profit possibilities. The factors that determine capital formation in peacetime can be almost entirely neglected and attention concentrated on productive potentialities. Finally, possible discrepancies between the amount consumers want to spend and the value, at specified prices, of the goods available for purchase are so large that even substantial errors of estimate will not alter major policy implications.

The development of methods for estimating the gap and the apparent usefulness of the resulting estimates for public policy during wartime have led many to suppose that a new technique has been developed for guiding public policy in peacetime. As the preceding paragraph indicates, this is an illusion. Gap analysis has added nothing to our understanding of economic change. We know no more now about how the business cycle runs its course than we did before. The special circumstances of a war period make it possible to use this imperfect knowledge to construct quantitative estimates that are useful for policy purposes. When these special circumstances have passed, the problems that plagued us before will plague us again.

Washington, D.C.

THE MEASUREMENT OF STATISTICAL COST FUNCTIONS: AN APPRAISAL OF SOME RECENT CONTRIBUTIONS[1]

By HANS STAEHLE

"When you cannot measure, your knowledge is of a meager and unsatisfactory kind." This famous statement of Lord Kelvin's may be paraphrased to the effect that, whenever attempts at measurement of previously unmeasured quantities and relationships are made, understanding and knowledge, if only of the complexities of the subject, are certain to be furthered. I shall pass in review, and appraise, a recent newcomer in the long series of efforts at quantification in economics, the literature on statistical cost functions.

The subject invites comparison with a closely associated development, the measurement of demand functions. From Gregory King to Marschak's most recent contribution, the process has been one of ever closer interpenetration of facts and theory. It is typical, for instance, that even to Marshall, aware though he was of the influence of factors other than price, elasticity of demand exclusively meant elasticity with respect to price, all other factors expressing their influence through either shifts or distortions in that price-quantity function. Marshall never used the concept of income-elasticity of demand. It was for H. L. Moore, the econometrician, to develop the idea of generalized partial elasticity coefficients of demand. As to the particular dependence of demand upon income and its elasticity, a relatively recent, and essentially measurement-inspired addition to the economist's toolbox, its possibilities for the further development of theoretical reasoning have already been exploited by Bowley and Allen, and have certainly contributed to shape Hicks's ideas. In other words, Marshall, the theorist, could afford to be content with stating *the* "law of demand" *ceteris paribus*. But attempts at measurement very soon made it necessary to find out what exactly the more important ones among the "other things" really were. For measurement of the price-quantity function is possible only if the influence of the *cetera* is successfully eliminated, and in order to eliminate we must know *what* and *how much*. The devices invented for the purpose of isolating what to Marshall was *the* law of demand have in turn proved stimulating to reasoning of a purely theoretical kind.

Later I shall examine whether a similar development can be expected

[1] A paper presented at a joint meeting of the American Economic Association and the Econometric Society, held in New York, December 29, 1941.

in consequence of past and present endeavors in the field of cost measurements.

Similar in this respect to the theory of consumers' choices, the theory of short-run producers' behavior proceeds on the basis of a simple postulate of rationality. As Cournot put it in 1838, "the producer [he was speaking of a monopolist] will always stop [expanding his output] when the increase in expense exceeds the increase in receipts"; or, as we would say today, when marginal cost (increasing or constant) equals marginal revenue (constant or decreasing). Cournot then goes on to say that he will scarcely have occasion to consider directly the total-cost function, but only its derivative, *i.e.*, marginal costs, the shape of which exercises the largest influence upon the solution of the principal problems of the science of economics.[2]

It is not idle to quote these remarks, not only because it never *can* be idle to read and quote Cournot; they also directly apply to all the statistical work which has been done in our field. Although each one of the authors finds it necessary to start out by measuring the total-cost function, all their work aims in the end at determining short-run marginal costs as a function of output. All these studies, in other words, by endeavoring to find a numerical expression for the function connecting marginal costs with output, are in fact, if not in intention, attempting to throw light upon the rationality of entrepreneurs' behavior. It would indeed be difficult to see why, if not for that reason, the measurements are undertaken.

In reviewing the literature on the subject I cannot hope to be complete. I shall therefore first list what appear to be the main contributions, and then briefly consider what methods were used to construct the relationship between output and costs; what concrete results have been reached, and what significance these results possess in relation to (1) the goal of the measurement itself, (2) business practice, and (3) cost theory. In a final section I shall try to speculate as to future possibilities.

I

Every field has its pioneers. With due reservation regarding the probability that Professor Viner will soon discover, if he has not already done so, a still earlier contribution, I wish to discuss as the first item in my list a brief article by an Austrian writer, Wilhelm von Nördling, on "Le Prix de Revient des Transports par Chemin de Fer" (Cost of Production of Transportation by Railroad").[3] That article

[2] A. Cournot, *Principes Mathématiques de la Théorie des Richesses* (Paris, 1838), p. 65; Bacon's translation, p. 59.

[3] Published in the *Annales des Ponts et Chaussées* for 1886 (1[er] sémestre), pp. 292-303.

must not be considered as a *curiosum* only. Its scientific value, even for the present day, will become apparent in the summary that I shall give of it later. May I merely mention that I found it quoted in an important lecture delivered by Emile Cheysson, the well-known French social reformer and pupil of Le Play, under the title of *La Statistique Géométrique, Méthode pour la Solution des Problèmes Commerciaux et Industriels* ("Geometrical Statistics, A Method for the Solution of Commercial and Industrial Problems")[4] in which Cheysson not only evolves a scientific program which sounds very much like Frisch's introductory address at the first meeting of the Econometric Society at Lausanne in 1931,[5] but also attempts to determine the Cournot point in a concrete statistical case. It is of interest to note that, in the article devoted to Cheysson in the *Encyclopaedia of the Social Sciences*[6] it is said that he "contributed nothing new to sociology or economics."

My second item is a contribution by Ehrke and Schneider published in 1933, in the former's book on *Overproduction in the Cement Industry*.[7]

I shall further consider the studies by Yntema,[8] and Ezekiel and Wylie,[9] on the United States Steel Corporation, both published in 1940, and, of course, Dean's various studies, the first of which appeared in 1936.[10]

I shall have no time to consider the various studies dealing with farm management problems,[11] nor the so-called break-even charts de-

In the *Annales*, the author's name is, with typically French neglect for "umlaut," given as "W. Nordling, ancien directeur général des chemins de fer au Ministère du Commerce à Vienne." There is no doubt, however, that W. Nordling is identical with Wilhelm von Nördling, k.k. Sectionschef und General-Director des österr. Eisenbahnwesens a.D., who in 1885 published a book *Die Selbstkosten des Eisenbahn-Transportes und die Wasserstrassen-Frage in Frankreich, Preussen und Oesterreich*, Vienna. This book, though full of statistical data, contains no study of cost functions.

veloped by, *e.g.*, Bolza[12] and Rautenstrauch,[13] nor finally the important work of Schmalenbach[14] and his school.[15] I also shall have to omit consideration of one attempt to measure a long-run cost curve (or envelope function) which Dean has produced but not yet published.

II

Granting these limitations of the subject, the great similarity in the problems encountered by the various authors, and in the methods they chose to solve them, suggests something of a necessity inherent in their task.

It is the aim of each one of these writers to isolate, from among the many factors that influence costs, the *net* influence of changes in the rate of output. In order to do this, each one attacks the problem by studying total costs, though they all are also, if not mainly, interested in marginal costs. Each one (with the exception of Ezekiel-Wylie and Ehrke-Schneider) runs up against the problem of measuring the volume of a diversified output. Each one has to face the problem of "technological change," and of possible change in the size of equipment, as one of the major factors to be eliminated. Finally, each one is compelled to consider the separation of costs which are not in the most immediate sense direct ones into those which depend on the lapse of time, and those which depend on utilization.

Von Nördling definitely sets out to obtain the relationship between costs and output when equipment is given. He carefully points out that what matters is not average cost, but only "the increment in expenditure necessary to transport one ton-kilometre *more* or, which amounts to the same thing, the saving that would be consequent upon the transportation of one ton-kilometre *less*." "Interest on invested capital," he goes on to say, "will not be part of costs thus understood, for interest is a permanent, invariable charge, independent of tonnage." He is aware of the problem involved in measuring output, consisting as it does of both passenger and merchandise traffic, and he adopts, after detailed justification, the convention of giving equal weight to a ton-kilometre of merchandise and a passenger-kilometre. Among the reasons for the adoption of this weighting system are considerations of the relative variable costs per unit. He then chooses from among the various railway systems existing in Austria at that time those for

[15] Reinhard Hildebrandt, Herbert Peiser, and others.

which in at least two, not necessarily consecutive, years the length of line operated remained as nearly constant as possible while at the same time large variations in the volume of transportation occurred;[16] and from the cost information available for the years thus chosen he then determines the total number of ton-kilometres supplied during the year (x) and the total variable costs (*i.e.*, other than interest on bonds) (y) per kilometre operated. He shows himself surprised and delighted—and both these emotions are fully justified—to find that these points, though relating to various different enterprises, when plotted in a single graph, very closely approximated a continuous function, showing when extrapolated a small intercept with the cost axis, and a constantly decreasing slope. He correctly identifies the slope of the radius vector as average cost per unit (y/x), and the slope of the tangent to his function as marginal cost (dy/dx). And then he does something very surprising: he writes the ratio of marginal and average cost thus: $\frac{x}{y}\frac{dy}{dx}$

Though unwittingly, von Nördling thus seems to be the first man to have printed the celebrated elasticity formula. For although Marshall found it on a Palermo hotel roof in 1881,[17] he did not publish it until 1890, in the first edition of the *Principles*. As to von Nördling, he merely uses it to study the fluctuation of the ratio of marginal to average costs over the observed range of output (where he finds it to be consistently less than unity) and to predict that it would increase to unity if observations for larger output rates were available.

This brief summary of von Nördling's article is far from exhausting all that is of interest in it. But it is sufficient to show that his results are far from negligible, that he saw and successfully solved each one of the major problems above listed, and that in at least one important respect he went beyond what has since been done in this field: he attempted a comparison of cost conditions in firms belonging to the same industry, a suggestion which seems full of promise, as I shall mention in my concluding section.[18]

It is now necessary to pass to a brief consideration of later con-

[16] Compare this to Dean's *Leather Belt Shop* study, p. 11: "The period . . . was chosen because it fulfilled the following conditions most satisfactorily: (1) The rate of output and other measurable cost determinants varied sufficiently to yield observations over a wide range. . . . (3) The plant and equipment remained unchanged during the analysis period, permitting the observation of short-run adjustments uninfluenced by long-run changes. . . ."

[17] A. C. Pigou, ed., *Memorials of Alfred Marshall* (London, 1925), p. 45.

[18] The only other attempt in this direction, though seriously imperfect in other respects, is a hitherto unpublished paper by Ernest M. Doblin who investigated costs in different steel companies.

tributions. A detailed description, however, seems unnecessary, since the relevant publications are easily available and I therefore assume that they are known.

The common basic material seems to consist of data taken from the accounting records either as published, or directly. In some cases, adjustments were made to redistribute depreciation charges in what seemed to be a more rational way. Efforts were also made to ensure that costs and output data related to the same unit period. Finally, wherever possible and necessary, the cost data were corrected for changes in factor prices, a practice on which I shall make some comments later. All this, however, though obviously of great consequence for the results, is neither very startling nor very interesting. I have nothing worthy of mention to offer in these respects and had better refer for a thorough treatment of some of them to a recent article by C. Reinold Noyes.[19] The two real *problems* in all this seem to be the measurement of output when production is diversified, and the elimination of technological change, and/or of changing size of the firm when that sort of thing occurs.

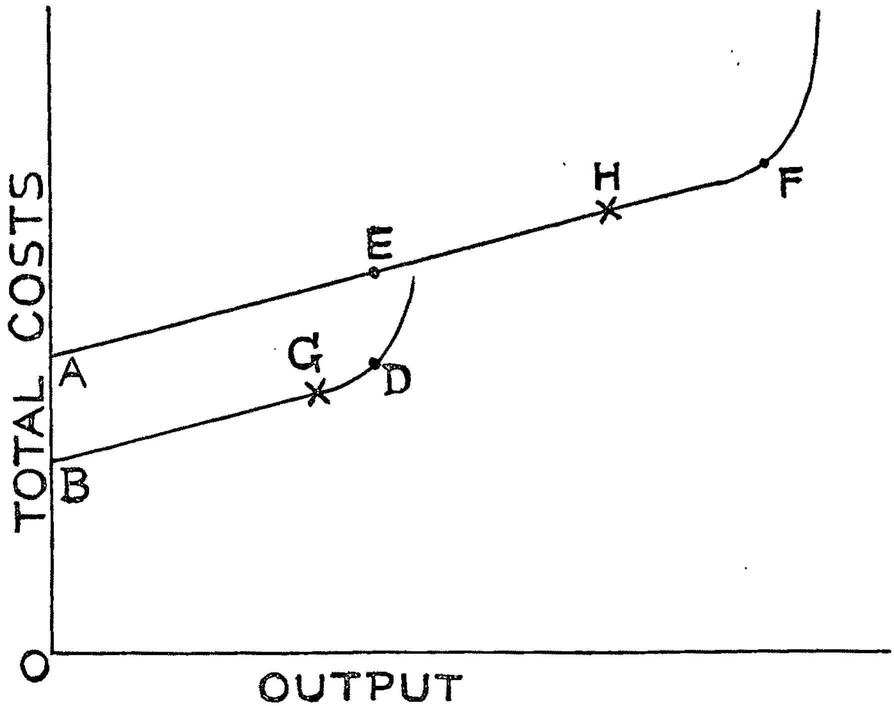
First, as regards measuring output (a problem absent in Ehrke-Schneider's case, but present everywhere else), the tendency often is toward solving it by weighting the quantity ratios relating to the various commodities by the relative direct, or variable, costs to which they respectively give rise. This practice seems highly objectionable, though it is difficult to see what other solution could be suggested. It indeed amounts to determining output by costs, *i.e.*, to introducing a spurious dependence where measurement of an independent relationship is really wanted. Nor could that problem easily be solved, as far as I can see, by any sort of correlation set-up.

Secondly, concerning technological change, the difficulties are truly insurmountable. There comes into being, of course, a new cost, if not a new production function, whenever such change occurs, and no amount of assuming, or fitting of trends to residuals will really do. Yntema has attempted the latter, and, without now going into a detailed criticism of his procedure, I merely wish to announce the appearance in a forthcoming number of the *Review of Economic Statistics* of a very thorough appraisal of both this and other aspects of Yntema's study by Caleb Smith.

Similarly embarrassing is the problem of changes in the size of the firm. Yntema, as well as Ezekiel-Wylie, did not do much, if anything,

[19] "Certain Problems in the Empirical Study of Costs," *Am. Econ. Rev.*, vol. XXXI, Sept., 1941, pp. 473-92. The same study also appeared as a "Memorandum on Costs in Relation to Output" as an appendix to Joel Dean's study of a leather belt shop, above quoted.

about it. And yet it is important. For, even though technique may remain constant, Schneider's "law of harmony"[20] will apply. That law states that full harmony in the structure of the enterprise only exists if an increase in fixed costs produces no more than a proportional increase in the rate of output possible without running into increasing average costs. Or, in other words, minimum average costs may still be lowered, given marginal costs, as long as full harmony is not realized. Graphically, if in the adjoining diagram AB/BO < EF/BD, where



BD = AE, harmony has not been reached. Yntema, to the extent that he failed to take account of variations in the size of U. S. Steel during his period of observation, thus obviously runs the risk of overstating his marginal costs. Whether U. S. Steel during the relevant years was increasing or decreasing, Yntema's results may well be of the nature of points G and H in the graph.

As to Ezekiel-Wylie, they mostly have used percentage of capacity as the independent variable. But though satisfactory in that it *seems* to settle everything, this device is very doubtful, in the light of Ter-

[20] See Ehrke, *loc. cit.*, where Schneider (p. 290, footnote) attributes the first formulation of this law to Ivar Jantzen. A German translation of the most relevant parts of Jantzen's original article is available in Erich Schneider, *Theorie der Produktion* (Vienna, 1934), pp. 83-92.

borgh's excellent remarks[21] on the measurement of capacity even in ordinary plants. His reasons apply *a fortiori* to U. S. Steel. Moreover, the device does not do away with the point mentioned in the previous paragraph.

Most other authors solve this problem by carefully avoiding it, *i.e.*, by choosing their firms and periods such that both technological change and variations in size are absent, which indeed also is a solution, though not a very satisfying one.

I may conclude this very sketchy review by mentioning the very high quality of the statistical work done by Dean. This, however, by no means exempts his results from the criticism which I shall later direct against the significance of all these studies.

Now as regards the results, I already mentioned von Nördling's. Yntema, Dean, and Ehrke-Schneider end up with linear total-cost functions, Ezekiel-Wylie with a function which exhibits a decreasing rate of increase. The latter result, I would not take too seriously. As Mosak[22] and others[23] have pointed out, plausibility is not one of its outstanding features.

It is, finally, worth mentioning that Ehrke-Schneider are the only ones to have secured observations on those extreme reaches of the total cost curve where average costs decidedly increase. But it took the *maximum maximorum* in relative cyclical position to make that possible. Their cement factory worked beyond optimum capacity during two months out of a period of about fifty years, at the top not only of the Juglar, but also of the Kondratieff, in 1873.

III

There is no reason, on grounds of theory, to be particularly upset by the conclusion which several of our authors have reached, namely, that marginal costs, instead of being U-shaped, seem to be constant over the whole of the observed range which, however, admittedly stops short of the probable point of optimum utilization of plant. All that this means is that an economic system in which such a condition holds rather generally, will be less stable than another in which U-shaped marginal costs predominate. And not one of the more competent theorists would need more than a moment's notice to invent and build into a "model" the compensating stabilizers required to approximate that model ever more intimately to "reality" which (as it well known) does not show uninterrupted series of explosions but some sort of

stability. From under *that* old top-hat we may, to use Hick's own image, confidently expect to be blessed with many more generations of lively rabbits. Economic theory, in short, cannot, quite apart from the Mises position, so easily be uprooted by any facts. In the particular case of constant marginal costs we are, thanks to Stigler,[24] in a position to look with equanimity upon any case of total-cost linearity that future measurements may grind out.

This, however, does not exempt us entirely from a consideration of the validity of the results so far presented. In fact, there is considerable room for doubting precisely their linearity aspect. An impressive array of arguments may be marshalled in this connection. I shall mention only a few points.

1. As Ruggles[25] has shown, very slight deviations from linearity in the total-cost function would be sufficient to impinge curvature upon the marginal cost curve.

2. Such deviations from linearity may easily occur for a number of reasons. For instance, the practice of straight-line depreciation fails to allow for the dependence of physical wear and tear upon output, thus understating costs at high, and overstating them at low, output levels. And negligible though that may appear, it might be just enough to confer upon the total-cost function that small amount of inverted S-shapedness which would suffice to bend marginal costs into their conventional U-shapes.

Furthermore, as Smith brings out in his forthcoming paper already quoted, in the event of a fairly long, say one-year, unit period, if the output is not spread evenly over each unit period, the use of the average rate of output during the period assumes a linear cost function and by this assumption biases the statistically determined cost function toward linearity, since the midpoint of a secant connecting any two points on a curve whose second derivative does not change sign lies closer to a straight line connecting the endpoints of the curve than does the corresponding point of the curve itself.

As Smith also shows, if costs are adjusted for changes in factor prices to any given period, this runs counter to the fundamental assumption of rationality in entrepreneurs' behavior and indeed destroys what evidence there may be of it in this important respect. If, in other words, the combination of factors used in the given period (to the prices of which the adjustment is made) was the most efficient one possible at the prices of that period, then costs in all other periods, when relative factor prices were different, would be overstated. This

[25] R. Ruggles, "The Concept of Linear Cost-Output Regressions," *Am. Econ. Rev.*, vol. XXXI, June, 1941, pp. 332-35.

point of Smith's is, I believe, quite realistic in that, in addition to Stigler's type of flexibility built into a plant which would flatten out the average cost curve, possibly at the price of a higher minimum level, there may be present another sort of flexibility by which an identical output may be obtainable with different factor combinations, choice between which would be guided by the relative factor prices. This would, after revaluation of the real cost elements at constant factor prices, lead to a maximum and a minimum level of costs for each level of output, thus making for a zone, rather than a single-valued cost function, in the statistical results. The width of that zone would depend upon (1) the "flexibility" of this special sort of which the plant was capable, and (2) the amount of variation in relative factor prices that occurred during the period of observations.

3. If the total-cost function, even after allowance for the above and any other conceivable points, should still insist upon being linear, it would not yet follow that marginal costs must be constant. For, as Barone[26] remarks in connection with Pareto's law of income distributions, "it is not safe to draw, by means of analytical transformations, other laws from an empirical law obtained by interpolations because one may in so doing end up with results completely divergent from reality." To his unsophisticated mind that still seemed to matter. This point of Barone's has been elucidated by Haavelmo in a recent paper.[27]

Arguments of the above type are plentiful and to be found in almost any treatment of our subject. To the extent that they apply to any special case they, of course, damage not only the linearity of the function derived but also the function itself. More particularly with respect to theory, this whole situation is very interesting. On the one hand, many reasons may be given why the statistical results, however carefully elaborated, may be spurious. On the other hand, however, there is also the tendency on the part of theorists, exemplified by Stigler, to build up a defense against possible future confirmation and consolidation of what, though itself still but shakily established, seems to contradict an assumption conventionally made in non-statistical reasoning. It is an interesting example of the inner workings of scientific progress.

IV

The discussion so far has been in terms of the reliability of the statistical results in relation to the functions which they claim to

[26] Enrico Barone, "Principi di Economia Finanziaria," now available as vol. III of *Le Opere Economiche* (Bologna, 1937), p. 55.

[27] Trygve Haavelmo, *On the Theory and Measurement of Economic Relations* (Cambridge, 1941, multigraphed), especially pp. 19 *ff*.

represent, and also in relation to the conventional representation of such functions in non-statistical reasoning. The following remarks will bear upon the significance of these results in a somewhat wider sense.

The final aim of both cost theory and measurement is, of course, and could not be anything else but a better understanding of entrepreneurs' behavior. There is no room for doubting that every entrepreneur perfectly realizes that, as long as he can increase his receipts more than he increases his costs by expanding his rate of output, it will be in his interest to do so under any given set of conditions which is likely to remain unchanged for some time to come. There is, however, considerable room for suspecting in the first place that, even abstracting from expected changes, entrepreneurs do not use marginal costs as *we* measure them in the application of that rationality principle. If that were so, it would not take long and painstaking research to discover marginal costs.

In the second place, even if actual objective marginal costs were known to entrepreneurs (as they quite probably are not), it might not be good policy to work at a rate of output which would maximize profits in the classical short-run fashion. For, although it is quite true that "in the long run we are all dead," that strictly applies to the long run only, and the likelihood of relief from duty through death does not normally enter an entrepreneurs' business calculations. Provision must therefore be made for the period of time which presumably lies between the present and the date of death. There is, for instance, the question of overhead costs. We tell our imaginary enterprisers not to worry about overhead costs in making current business decisions. But real entrepreneurs know that overhead cannot all be handled by mere balance sheet adjustments: interest must be paid in hard cash at stated dates. And although to economists it may appear as perfectly obstinate to refuse to accept so obvious a distinction as that between costs which are a function of output and costs which depend only on the lapse of time, there is *some* wisdom in a policy which attempts to keep cash ready for the moment interest charges are due. So much wisdom, indeed, that even the venerable principle that no production really ought to take place unless at least variable costs are covered by expected receipts might break down under the stress of its weight.

I should not, however, if I were asked for it, give the advice to handle the problem by a mathematical analysis of the conditions that would maximize profits over time (*pace* Tintner). I would rather be inclined, in this particular respect as well as more generally in relation to the determination of cost functions, to look for another type of solution. I often wonder if statistical theories and techniques whose

admirable development cannot fail to impress anybody *qua* intellectual exploit have not brought about a propensity to employ refined methods of inference where direct and complete knowledge would be readily available. Why go to all the trouble of measuring cost functions for an individual firm when it would be quite feasible to obtain from entrepreneurs (at any rate from those who open their books to the econometricians) the very best of information concerning the reasons for their decisions? Why not ask them directly, with all the caution required to avoid suggested answers, rather than try to infer in a most clever, but certainly roundabout, and probably incomplete way from dead records what probably is going to be a result irrelevant to actual business men's decisions?

I am not overlooking that the whole distinction between objective and subjective marginal costs and rationality would vanish in the event that private business men were replaced by government managers. The latter, being, I presume, less urgently concerned with the making of profits and the avoiding of losses, may possibly find the necessary leisure and be possessed of sufficient detachment to study marginal costs as they *really* are. And it is quite conceivable that the possibility of hinging price policies upon actual objective marginal costs would represent one of the major trumps in favor of socialism.

V

In this section, I wish to say a few words as to possibilities for future development in this line of inquiry.

In the study of demand, actual individual behavior is the deepest-lying level to which we can dig. Everything beyond is largely in the nature of speculation. I say largely, and not completely, remembering Thurstone's valiant attempt[28] to measure indifference curves by means of psychological experimentation. Nevertheless, it remains true that in that field, where the basic postulate of rationality is strictly analogous to the one which underlies supply theory, the greater part of the operation of this rationality takes place in regions where direct measurement is at least difficult. And being in a position to measure, so to speak, only one end of it, we are free to reconstruct the rest in agreement with any desired schema, *e.g.*, our own conventional consumers' equilibrium, without much fear of contradiction.

The situation is *not* the same in the theory of supply. Costs here, as expenditures there, represent only one of two pillars of the short-run rationality principle. But the other, receipts, or revenues, is observable, at least in principle. And being observable, it has to be observed if we

[28] L. L. Thurstone, "The Indifference Function," *Jour. of Soc. Psych.*, vol. II, 1931, pp. 139-67.

wish to avoid the absurdity of results obtained through application of our rationality principle to information on costs alone, a point which has so strikingly been shown by Leontief.[29]

Now I do not mean to say that any *statistical* approach to total, average, or marginal revenue functions for the firm is advisable. On the contrary, the doubts above uttered as to the significance of statistical cost functions fully apply to similar analyses of receipts. In addition, there are excellent reasons on the theoretical level which speak against any such venture. I am referring to the articles by Hall and Hitch[30] and Sweezy,[31] the simultaneous appearance of which again offers an example of ideas which are *in the air* and find independent and similar expression. And Sweezy's contribution in particular has the virtue of not being written in adaptation to, or in defense against, any previous findings which more or less explicitly claimed to disable preëxisting theoretical expectations. In consequence it may safely be said that there are excellent reasons why the subjective, *i.e.*, actually operative, demand curves should have a kink at the level of the current price. I should therefore again advocate some method of inquiry similar to that used by the Oxford economists, and be inclined to expect significant results. These results might be even more valuable if they could be expanded horizontally, following von Nördling's suggestion, so as to cover conditions, both of cost and revenue, for firms operating in the same or immediately related markets.

Finally, there are no reasons why at the cost end of the matter we should stop at the cost function. Two years ago, Stigler[32] proposed another approach to cost functions, *i.e.*, *via* production functions, such as might be established by engineers. While that still remains a useful suggestion, there are reasons to hope that another type of production function, more diversified than Douglas's, may soon become available, and from these it would be possible to derive cost functions typical for particular industries. The literature on statistical cost functions so far produced has certainly, as all measurements are bound to do, enhanced understanding and awareness of the complexity of the subject. But I cannot help thinking that it also represents a case which bears out just that, and not much else.

MODERN ECONOMICS AND THE INTRODUCTORY COURSE

By Richard Clemence *and* Francis S. Doody

I

The repercussions of events which shake the whole civilized world eventually make themselves felt in the economics classroom. Students, in larger and larger numbers, are looking to the teacher of economics for an explanation of the great changes that are everywhere taking place.

In quieter times students begin their study of economics without a great deal of enthusiasm, and the first few meetings of the class often succeed in putting an end to whatever small interest in the subject they may originally have had. In days like the present, however, the teacher of economics, in his annual retreat from reality, finds it increasingly difficult to take his students with him. He is brought face to face with responsibilities which become no easy matter to evade. Not that most teachers are particularly anxious to evade their responsibilities to their students, but in more peaceful days they may easily do so without being aware of the fact. This is no longer possible in periods of rapid and violent change, and the teacher of economics finds himself in a difficult and embarrassing position. The teacher himself, we hope to make clear, is not wholly to blame for his predicament. It is but one of the symptoms of the generally unsatisfactory state into which the course in introductory economics has fallen. Indications are not lacking that there is a growing appreciation of the inadequacy of much of our teaching, and the time may well have been reached for a clear formulation of the issues.

The teacher of economics has accepted a position carrying with it great responsibilities, for he claims to possess both an understanding of the course of events beyond that of ordinary men, and the ability to impart this knowledge to others. The results of current teaching in most courses in general economics, however, make it difficult to believe that most teachers are living up to their claims. Economists, of course, do not pretend to be able to explain everything important that is happening in the world of reality. Yet, nearly every competent teacher of economics knows vastly more of vital interest to his students than he ever tells them. Our students need all the help we can give them toward an understanding of the forces shaping the future of America and of the world, but we seem obstinately determined to talk about anything and everything else.

Although dissatisfaction with the teaching of general economics is widespread, attempts to improve the situation have not been notably successful. The fundamental nature of our difficulties has not been generally appreciated, and attention has been too largely focused upon obvious, but superficial, defects. For our efforts at reform to be effective it is necessary to recognize the character of our troubles, and to determine the causes of them, before we undertake a course of action. No attempt will be made here to review the numerous shortcomings which have been widely discussed elsewhere, and of which most of us are sufficiently aware. Instead, we shall deal with the broader aspects of contemporary courses, and try to discover the more basic inadequacies, and the reasons why they continue to exist.

Courses in general economics utilize materials which may be crudely classified into two divisions: theory and descriptive matter. Most of the theory taught in introductory courses is the sort usually called static theory. This kind of theory is ordinarily applied to beginning students far beyond the point of diminishing returns. The study of the determination of value and price in perfect commodity and factor markets while dynamic forces are locked up in *ceteris paribus* can be significant to students only if it is frequently emphasized that these forces have been impounded, and only if they are eventually released. If theory is to make a major contribution to the students' understanding of reality, the dynamic forces ought to be freed at the earliest possible moment. This, however, is not usually done. The discussion of value theory goes on in a vacuum, and complications are often introduced which produce a spurious and very confusing illusion of reality. Monopolistic competition, for example, is much more like reality than the purely competitive analysis, but it is not a complete explanation of the real world and is not intended to be. Nevertheless, the refinements of monopolistic competition are often pursued in the classroom until a definite impression has been created that static analysis is much more powerful than it is in fact.

The inadequacy of the customary treatment of theory appears most clearly in those courses which devote some time to what are known as "economic problems." A glance at nearly any textbook of economic problems is sufficient to show that such books contain not merely statements of problems, but also what purport to be solutions of them. Here is implicit recognition of the fact that students cannot actually analyze economic problems, even after the issues have been defined and oversimplified for them. It is not to be wondered at that this should be true. They have learned methods of analysis that apply almost exclusively to stationary states, whereas the problems are those of a dynamic world. It might be supposed that an attempt to apply theory

to reality would make clear to students the extent to which static theory can explain actual situations and the extent to which it cannot. This is rarely true, however, for most discussions of problems make little or no attempt to apply the theories previously taught. Indeed, the problems very often degenerate into long and detailed discourses on the history, present condition, and future prospects of as many different entities as classification can produce.

The use of problems is, in any case, open to serious objection. To reduce the difficulties of the real world to a number of separate issues is to make it almost impossible to impress upon students the concept of an evolving system of interrelated and interacting elements. Anyone who is taught to think of the difficulties of the world as consisting of a number of clear-cut problems to each of which he has a proper solution is being poorly prepared to live in a real world so vastly different.

The attempt sometimes made to mix theory and problems together, instead of dealing with the two separately, is liable to no more temperate criticism. The root of the difficulty is the inadequacy of the static method for the analysis of dynamic problems, however introduced, and both the virtues and the limitations of the static method are hopelessly obscured by the combinations of economic principle, native cunning, and shrewd observation employed in reaching the standard solutions.

Static theory possesses squatter's rights in the introductory course which have been little disturbed by recent advances in the field of business cycle analysis. Even this tentative approach to reality is customarily postponed until the dying moments of the course, and it is then dismissed without any suggestion that it constitutes the principal body of theory applicable to most practical situations. The explanation for this peculiar condition is somewhat obscure. Certainly few of us feel that we have nothing to say to our students about cyclical fluctuations. Nor is it true that students cannot understand business cycles until they have explored all the ramifications of static theory. Indeed, prosperity and depression mean more to students at the beginning of their study of economics than do the topics ordinarily first discussed.

Strangely enough, the excuse usually offered for our failure to incorporate business cycle theory into the introductory course is that there are still too many differences of opinion concerning it among economists themselves. The weakness of this argument is evident when we consider the far-reaching changes which have recently been made in equilibrium theory, and the acrimonious discussions which have taken place concerning them. Yet it has not been seriously proposed that we stop teaching value theory in the classroom until everyone is as well satisfied with it as was John Stuart Mill.

While we are occupied in perfecting our defenses against the en-

croachment of business cycle theory upon the static analysis in our elementary courses, the battle against realism is in danger of being lost through the activities of enemy agents behind our lines. Nothing in recent years has aroused more controversy among economists than the publication of Mr. Keynes's *General Theory* and the literature associated with it. Since the principal work of the Keynesian group has been the analysis of a long-run equilibrium accompanied by less than full employment of the factors of production, their treatment has impinged upon our traditional teaching at one of its most vulnerable points. This is not the place to consider the accomplishments of the Keynesians in detail; opinion is still divided concerning the significance of their work. Our interest is in the contributions which the use of the Keynesian methods and materials may make to the teaching of elementary economics.

From this standpoint the use of the Keynesian analysis provides a means of supplementing the traditional static theory with the study of a model closer, in some respects, to reality. The concepts developed in this analysis may also be applied to short-run phenomena, and some teachers are doing this with a good deal of success. It seems likely that the teacher of general economics who himself likes to think in Keynesian terms will find their use in the classroom effective. Others may be more impressed by the ease with which false issues, such as the equality or inequality of savings and investment, may be pursued, and the facility with which students may be led to an uncritical acceptance of economic panaceas. Those teachers who have doubts concerning the use of the Keynesian system in the introductory course may eventually find themselves forced to accept much of it unless they are able to propose a more satisfactory alternative.

There is little novelty in the charge that much of the theory taught in elementary courses is sterile. It is not so generally recognized that a great part of the descriptive material ordinarily presented is liable to the same indictment. Obviously some discussion of current economic institutions is essential in any course in general economics. If a serious effort is to be made to teach useful methods of economic analysis, description must supplement the theories to give them their proper significance. All too often, however, an exhaustive account of the contemporary scene is undertaken with little or no attempt at theoretical analysis. Many courses in general economics have become so cluttered with descriptions of petty business practices, production policies of individual firms, personnel management, marketing techniques, and the like, as to give the impression that an attempt is being made to divert attention from fundamental inadequacies by talking loudly about things which are hardly economics at all.

Even when description is confined to economic entities, students are

frequently asked to learn much more than their teacher himself can remember from one year to the next. Large masses of facts and figures tend to be taught without any clear conception of their relevance and probable permanence. They are, of course, descriptive of reality but, as commonly used, they contribute very little to the students' understanding of it. It does not constitute an improvement in the course to make the wrong assignments longer and more difficult. Increasing emphasis on the particular and the trivial can only further obscure the general and the significant.

Descriptive matter, of course, is not confined to contemporary institutions, but includes historical material as well. It must be said that the treatment of history in the introductory course is more often than not a complete failure. A principal difficulty is that the discussion of history is seldom focused upon anything at all, to say nothing of the central problems of economics. The aim often seems to be to render to the student a factual account of such phenomena as the development of banking from the goldsmiths to the latest change in reserve requirements. Even when the origins and development of capitalism are explored, students very often fail to acquire the evolutionary point of view. This objective the study of history in the course in general economics ought always to achieve. One cannot expect that students will long remember the facts and dates they are taught, but they should always be left with a general conception of dynamic change and a feeling for the historical process in which their own present world is but a stage. Very often, however, the study of history leads rather to the belief that the process of history has culminated in the American capitalist system under which we may expect to live the remainder of our lives.

Another weakness of the ordinary treatment of history is that it fails to bring out the essential relation between theory and historical fact. Students are not shown how theory suggests ways in which to classify the facts of history, or how the apparently random facts of existence are brought into order through the use of explanatory models. It is not our view that history should be deleted from the course in general economics. Rather, we should seek to develop a method of integrating history and theory in order that the returns from both may be maximized. If historical material is to contribute, as it should, to the students' understanding of a world in motion, the forces making for economic change must not be allowed to lie unperceived under a blanket of meaningless generalities.

Another type of descriptive material commonly introduced into the elementary course has to do with current events and issues. Many courses end, for example, with a discussion of the New Deal, giving par-

ticular attention to the N. R. A., the A. A. A., and the abrogation of the gold clause. Apparently an annual revision of the subject-matter to include the latest bits of economic trivia is conceived by some as a method of making a static course dynamic. A daily reconstruction of the course to incorporate such changes as may have taken place during the night would seem to be the ultimate ideal. The treatment of current issues in the classroom is fruitful only if the students have sufficient background to see the issues in their proper perspective, and enough facility in economic analysis to formulate intelligent judgments for themselves. The fact that teachers often hesitate to raise controversial questions in class for fear they will bias their students is evidence enough that their students have not been properly trained. The reasons why students are not better prepared to deal with such matters have already been discussed. The situation is serious, for it is one of the functions of a course in economics to enable students to distinguish reason from prejudice. If we are not teaching them to do this in the cloistered atmosphere of the classroom, they are being poorly prepared to live in a world inhabited by increasingly clever pressure groups.

Perhaps the most conclusive evidence of our shortcomings is a simple truth of which nearly every teacher of economics is painfully aware. Intensely interested though he is himself in a subject inherently interesting, the economist has difficulty in arousing and holding the interest of his students from beginning to end of the course. He is forced to resort to all sorts of cunning devices in order to preserve the illusion that something is actually going forward in the classroom, and to keep his students from falling asleep. If some of us succeed in deceiving the unsophisticated, and leading them to believe that trivial things are important, it is small cause for congratulation. The plain fact is that we are not teaching our students what they want to know, and what they have a right to expect us to teach them.

It is somewhat easier to point out the nature of our difficulties than it is to discover the causes of them. The question would be less perplexing if economists were generally less competent, and if we could simply admit that they have nothing significant to say. But the study of economics has made considerable progress during the last half-century, and economists have reason to claim that they understand the world about them better than their predecessors of fifty years ago. The same claim, however, can hardly be made for many of their students. In spite of the progress our study has made, the teaching of general economics remains fundamentally what it was in Marshall's time.

One reason for this is that some of us are afraid our students cannot understand the things we know. It takes long years of study to

make a competent economist, and a beginning can hardly be made in a single year. It should be clear enough that a course in general economics will never make an economist out of anyone, and that a great many things economists find it helpful to know are of no use whatever to their students. But students do not have to learn all the useless things before they can comprehend the significant ones. If we insist upon our students starting over again where we began, we are imposing upon them a handicap which is totally unnecessary. It is the function of the teacher to teach his students that part of what he now knows that will be most valuable to them. There is no reason to think that they will be any less apt to learn the things they want to know than they are to learn those we are now trying to teach them.

A major cause of our difficulties is that a good deal of uncertainty exists concerning the proper aim of a course in general economics. Some would hold that we ought to teach our students how to make money. Another group takes the position that we should teach them how to spend it. There are also those who insist that our principal objective should be to teach our students a technique of thinking. With this technique they can perform what is called economic analysis, and solve economic problems. Opinion is again somewhat divided, however, as to whether the major aim should be to teach students to solve the problems encountered in advanced courses in economics, or the problems of the real world. Finally, a considerable number hold that the paramount consideration must be to teach our students about our economic institutions. If we can succeed in getting enough factual knowledge into their heads, it will never again be necessary for them to consult an encyclopedia.

The absence of a single definite objective has the unfortunate result that, in practice, we are often trying to do too many things at once. We attempt to prepare students for advanced study in the field of economics, for successful careers in the world of business, and for life as intelligent American citizens, all in one brief course. Obviously, so much simply cannot be done; the attempt can result only in failure. We would better concentrate all our time and energies on the achievement of some one of these ends instead of leaping into the saddle, like Leacock's horseman, and riding off in all directions.

But even when some single objective is precisely formulated the dead weight of tradition usually prevents its realization. Unless we can free ourselves from this burden at the outset, our attempts to modernize the teaching of general economics simply break down the integration of our subject-matter without disturbing the traditional outlook.

II

It is our conviction that reform in the field of economics teaching must begin with a restatement of the whole problem. The course in general economics requires a complete reorientation which cannot be achieved so long as we are dominated by an archaic point of view.

The general problem, briefly stated, is to determine the most effective method of teaching general economics to beginning students. Since a course in economics is only a part of the larger education of each student, it is unlikely that any single solution could be entirely satisfactory to everyone. Some students, for example, regard the introductory course as a preparation for more advanced studies in the field of economics. It may be that the tools and methods of economic analysis should receive more emphasis in a course designed for them than would be profitable for the rest. Whenever special courses can be offered to fit such special needs, or tutorial instruction can be used to supplement the work of the classroom, it is obviously desirable that these things be done. Unfortunately, however, they are seldom practically possible.

We are concerned throughout the present discussion with those students, forming the majority in most American colleges and universities, who take only one course in economics, and who must be taught in one year as much about the subject as they will ever learn in the classroom. It seems to be generally agreed that the provision of a satisfactory course for these students is one of our most pressing problems. Yet, it is not unfair to say, special attention is too often paid to the needs of some particular minority, while the majority are left to pick up such crumbs as may fall to them from the high table.

Our aim, then, is to determine how best to teach economics to students who will never study the subject systematically again. In only a few hours, constituting at the most a fourth of the students' time during a single academic year, they must be taught that part of what we know about economics that will be most valuable to them during the remainder of their lives. Necessarily, the choice of subject-matter will involve the rigorous exclusion of everything not of vital importance. The criteria of importance must be both relevance and permanence. Students are wasting their time if anything other than economics is permitted to occupy any considerable portion of the course, or if they are required to memorize data having only transitory significance.

There is no general consensus even among economists themselves concerning what is economics and what is not. Our science is still growing, and there is naturally some difference of opinion regarding its bounds. Indeed, it is open to question whether economics is properly

a science at all. We propose here to make use of a definition of our subject which departs somewhat from tradition. We define economics as *the study of the structure and operation of economic systems.*

Before we make use of this formulation as a basis for the choice of subject-matter in the introductory course, we shall say something concerning its advantages. It represents an attempt to give concreteness to the definition of economics, in order that it may be more meaningful to beginning students than those in common use. Experience in the classroom has shown that it does possess certain valuable attributes as a teaching device. In the first place, the definition may be introduced early in the course with some confidence that it will make a positive contribution to the students' understanding of the character of the subject they are going to study. Furthermore, the definition distinguishes between institutional and theoretical materials, and it leads to a ready appreciation of the relation of the more specialized divisions of the subject to the whole. Finally, the inclusion of an undefined term is purposeful; it focuses attention on the question of the nature of an economic system.

An economic system is defined as any set of arrangements by means of which a group of people attempt to satisfy their wants for scarce goods and services. This definition makes it easy to impress upon the student the complexity of the relationships between economic and social and political elements in the real world, and the necessity for abstraction involved in the very concept of an economic system. It is also possible to emphasize the fact that any economic system has definite boundaries only in our minds and never in reality, so that economic analysis alone cannot explain real phenomena without qualification. These highly important considerations are, of course, an old story to every economist, but it is very difficult to impress them upon beginning students. Definitions may often be developed for teaching purposes which, though imperfect from some points of view, are peculiarly useful in the educational process.

We return now to the choice of subject-matter. Any material is of some relevance if it contributes to an understanding of the structure and operation of economic systems. But to make the greatest contribution in the limited time available, it will be necessary to devote our principal attention to the American economy, and to study only the most important elements in its structure and operation. Further than this, the elements we select must be most important, not only at the present moment, but also in accounting for the changes in American capitalism which modify its structure and operation over time.

It has always been difficult enough to achieve any considerable integration of the subject-matter in the elementary course. If we deliber-

ately set for ourselves a task more ambitious than that traditionally undertaken, we run the risk of losing even such small continuity as still remains. It becomes more than ever essential to seek some unifying principle which can be made the focus of attention throughout the entire course; a core around which the study of economics can be built. What is most important, it must be, not a static element, but a dynamic one; an element, if possible, in relation to which the whole process of economic evolution can be significantly explained.

The one concept which best meets these requirements is, we believe, the national income. The entire course may be regarded as an attempt at the solution of a single economic problem. That problem is to explain the forces which determine the size and composition of the national income, its fluctuations over time, and its distribution in both space and time. To some extent this involves a return to the older view of economics as "political economy"; indeed, we are inquiring into the nature and causes of the wealth of nations. But we are no longer dealing with the economics of stationary states, and the analysis is more than an aggregative one. We are not proposing that the elementary course simply be made into a course in business cycles. Though business cycles necessarily occupy a more important place in our analysis than in the traditional one, they are far from being the sole topic of discussion.

We proceed now to a description of the course we are proposing. Our discussion is intended to be suggestive of what may be done, but the details are not of paramount importance and we would not insist that those we admit here are necessarily the best. It is evident that adequate support of our proposal would require the preparation of a textbook embodying the ideas we are putting forward here. We therefore wish to emphasize the fact that most of the necessary materials are already available, and that the principal objective is the development of a new point of view.

The national income is viewed as the resultant of the operation of the economic system over time, and reflects the changing structure of the system as it is modified by its own operation as well as by factors not purely economic. The explanation of the course of the national income and its distribution is made the object of economic analysis, and this explanation involves the study of the structure and operation of the American economic system.

We believe that statistical materials concerned with the national income of the United States since the early period may well be presented at the beginning of the course. The most effective method of introducing such materials is to provide the students with the necessary data and have them draw the simple graphs, using semi-logarithmic scales whenever rates of change are significant. The data first used are total

monetary and real national income, total population statistics, and per capita income figures. With graphs of these data before the class, it is remarkable how many significant questions are immediately raised by the students themselves. The study of economics has begun with facts from the real world, and these facts clearly require explanation. That student is dull indeed whose interest is not at once aroused.

At this early stage it is desirable to treat the data in general terms, calling attention to significant trends—explaining what is going to be attempted in the course, and how it is going to be done. Students not uncommonly pass a course in economics of the traditional sort without once having any clear conception of the relation of the parts to the whole or, in general, what all the commotion has been about. The difficulty with most discussions of these important matters is that they take place in a vacuum, and the students can do little more than try to memorize a number of abstract statements.

We suggest that the next step in the treatment be in terms of the concept of equilibrium, and that the student be given a clear comprehension of the limitations of the analysis, as well as an appreciation of its value for the understanding of many actual situations. There is considerable difference of opinion concerning the extent to which traditional theory contributes to an understanding of reality. It is our view that it does not accomplish nearly so much in the usual course as it can be made to do. To place the theory in its proper setting the question may be raised: Under what conditions would the national income remain constant over time, in composition, in size, and in distribution? The careful analysis of this problem serves to indicate the nature of equilibrium tendencies in the real world, and the conditions under which they may be expected to exert most influence. At the same time the basis is laid for the later treatment of the reasons why, in fact, a condition of equilibrium is never achieved by the whole system.

The discussion of equilibrium tendencies in the economy begins with a brief description of the principal institutions forming the structure of a capitalist system, with emphasis upon the free market. The relation of households and firms to the market is shown, and the forces which tend to bring them into equilibrium are analyzed for the customary time periods. The forms of business organization may be discussed here with particular reference to the meaning of a firm. The aim is to indicate the general character of the structure of the economy at the same time that its operation under given conditions is studied. It may be desirable to limit the scope of the discussion at this stage to the institutions of pure capitalism, and postpone the question of institutional change until the discussion of dynamic forces is undertaken.

The static analysis is developed for group equilibrium and for equi-

librium of the whole system. Value and distribution should be regarded as a single problem here, with no separate treatment of the different distributive shares. Emphasis upon the conditions necessary to the achievement of full system equilibrium forms the basis for the identification of frictions, which make ideal equilibrium impossible to reach, and of dynamic forces, which may set up cumulative movements away from such approximations to equilibrium as actually exist.

Only enough time should be spent on the static analysis to solve the problem with which it was introduced, and the discussion should move on at once to the treatment of dynamic change. This will involve the study, not only of business cycles in the ordinary sense, but of longer movements as well. We have found that a very effective method of treating these phenomena is in terms of the real and monetary national incomes and the interactions between them. With the introduction of movement into the system, the question of changes in the price level becomes significant, and this should be regarded as merely a part of the larger problem. Instead of introducing some one or several of the usual price-level formulae, we define the price level simply as the ratio of the monetary to the real national income. Price-level data now form the connecting link between these magnitudes, and the long-period rises and falls in the price level are related to the movements in output and the monetary circulation. This treatment has a number of advantages in teaching introductory economics. The analysis is simple enough to be readily understood, and at the same time it does not prevent the introduction of any complications that may be thought desirable. It also makes it impossible to divorce monetary theory from the real phenomena with which money is associated, and issues such as price-level stabilization are seen to involve the whole functioning of a capitalist economy.

Fluctuations in the monetary national income are explained in terms of investment and consumption, with data supplementing the theoretical treatment, and the function of credit in a capitalist system is developed. This leads to a study of credit institutions, the banking system, and central banking policies and controls. At no time are such institutions discussed as important in themselves, but an understanding of them is always seen as relevant to the principal problem.

The rôle of profits in a private enterprise economy is stressed and related to the incentives to invest. Here the relation of profits to factor prices may be shown, and the different distributive shares separately analyzed. The treatment makes full use of the shifting demand and cost curves developed in the short-run static analysis, and at the same time data are used to show the functional and personal distribution of income.

It is now desirable to deal with certain aspects of the institutional structure, such as trade unionism and collective bargaining, public finance, and international trade, in order to support the theoretical treatment and place it in its proper setting. These topics are often treated as a series of special problems, but their real relevance is developed by relating all of them to the national income. Fluctuations in trade union membership, for example, are seen to be associated with business activity and levels of employment. Public finance is seen to reflect the changing rôle of government with the evolution of capitalism, and international trade is related to levels of economic activity within the trading countries.

The discussion of international trade leads naturally to some comparison of the American economy to others. This may be done by presenting comparative data for the different aspects of their national incomes, and an examination of the resources of various economies may be undertaken. The resources of the United States cannot be made significant without reference to their relative importance in the world picture, and some indication of their influence upon the relative magnitude of our national income, as well as upon its composition.

The study of fluctuations in the levels of output, employment, and income could be profitably pursued during the remainder of the course. It is important, however, to make such use of the explanations developed as will contribute most to the students' understanding of reality. We believe this can best be done by applying what has been taught to a study of the historical process, and attempting to achieve a synthesis of economic theory and history.

The economic history of the United States consists essentially of a commentary upon the trends in the data already introduced into the course. History is therefore taught, not as an end in itself, but as necessary to the solution of the problem defined at the outset as the object of economic study. History should not be permitted to encroach upon the principal analysis, but should be subordinated to it, and only those historical facts introduced which have most significance for the explanation of the changing trends observed in the data. The dates to be emphasized are those associated with major changes in the behavior of the time series, and attention should be focused upon these series throughout the discussion. The changing character of the American economy should be related to the longer trends in the data, and the broad stages of capitalist development identified.

The concluding note of the course may well be a discussion of the relation of an economic system to the whole of society, and of the relation between capitalism and democracy. Capitalism will then be recognized as involving, not merely an economic organization, but a way

of life, and the various stages in the evolution of capitalism will be seen as phases in the development of our whole civilization. The teacher should make use of everything that has been taught by leading his students to think about the future of the United States and of the world, and about the important forces that are tending to shape that future. He should face his responsibilities with courage, and demonstrate that the study of economics can contribute to an understanding of life in a changing world.

Silvio Gesell's Monetary Theory of Social Reform

In spite of the attention which has been given to the writings of Silvio Gesell,[1] the stamped money reformer, the unifying basis of his work has, I think, been neither clearly stated nor satisfactorily elaborated. The relation between the theoretical and practical aspects of his analysis has been either ignored, misunderstood or distorted.

Gesell's objective as a social reformer was to attack *rentier* capitalism and to substitute in its place an interest-free society. To fortify his reform position Gesell developed a system of economic theory in which he tried to demonstrate that the nonutilization of resources and the presence of nonfunctional income are the inevitable accompaniments of prevailing financial institutions. The most important single phase of his theory as a whole is his theory of interest. In its critical aspect this theory represents an attempt to show that, in a system of conventional money, interest income is a payment to prevent the hoarding of money. In its positive aspect the theory is an attempt to show that the introduction of stamped money would eliminate "basic interest" and thus pave the way to an interest-free economy. The purpose of this note is to show that Gesell's theory in general and his theory of basic interest in particular represent an argument for his stamped money proposal. This may best be shown by indicating that the practical insight which led Gesell to propose a tax on money was chronologically as well as logically prior to his theoretical system.

That the practical aspect of Gesell's thought was chronologically prior is not difficult to demonstrate. In 1886, at the age of twenty-four, Gesell migrated from Europe to the Argentine to engage in foreign trade and small-scale manufacturing. There he witnessed one of the most speculative episodes in the history of modern capitalist development. The great boom from 1885 to 1890 preceded a long and severe depression which lasted for the duration of Gesell's stay in the South American republic. The frustration of industrial activity produced a strong current of resentment against the speculating financiers, brokers, stock jobbers and mortgagees. As one whose interests were directly affected, and as one whose indignation was aroused by this financial debauchery, Gesell participated actively in the opposition to the group interests which appeared to be responsible for the chaotic state of

affairs. His first publication, *Die Reformation im Muenzwesen als Bruecke zum Sozialen Staat*,[2] contained the kernel of his ideas on monetary policy. Between 1891 and 1898, Gesell published five other works on monetary policy,[3] but nothing specifically on monetary or general economic theory. These were the formative years of his career.

When Gesell returned to Europe in 1900 to reside in Switzerland and Germany, his practical reform proposals had already been worked out and published in all their essentials. The formulation of his theory came later. In 1911 he published *Die neue Lehre vom Geld und Zins*, which formed the theoretical basis for his system of social reform.[4]

A more detailed discussion is needed to indicate the logical, as distinguished from the chronological, relation of Gesell's program to his economic theory: first, because it has been the source of more misinterpretation of his position, and second, because of the somewhat more complicated nature of the problem. Keynes, for example, has reversed the relation between Gesell's theory and program. In discussing Gesell's theory of interest, Keynes says Gesell "carried his theory far enough to lead him . . . to the famous prescription of 'stamped' money."[5] Keynes conveys the impression that Gesell arrived at his practical suggestion in spite of a "great defect" in his theory, whereas it would be more accurate to say that Gesell's theory is not, in some important respects, an adequate explanation of his practical suggestion. His theory is a refinement of his insight that money should be forced to circulate by means of a periodic tax which would offset the preference of wealth owners for "hoarding" money rather than spending it for some form of consumable or productive wealth.

Gesell's contention that interest is a payment to prevent the "hoarding" of money classes his interest theory with the "exploitation" doctrines of other socialists. He regards the share of total social income represented by interest as a deduction from the income created by laborers, including industrial capitalists. His theory of interest is not, however, the same as the exploitation theory of Marx. Gesell's position is both anti-classical and anti-Marxian. Although he avowed himself a socialist and professed to be attacking capitalism as a whole, his anti-capitalistic position must be interpreted in terms of his definition of capitalism as "the interest exploiting system."[6] In this particular

References cited below are to the "Money Part."

[5] *General Theory*, pp. 356-57.

[6] Gesell's more technical definition of capitalism is, "An economic condition in which the demand for loan-money and real capital exceeds the supply and therefore gives rise to interest." *Natural Economic Order*, p. 110.

connection Gesell's position is similar to that of Gottfried Feder, who in 1923 was appointed by Hitler as the final judge of all doctrinal questions of the National Socialist Party. In Hitler's famous list of twenty-five points, one of the two points in bold-faced print calls for the "Brechung der Zinsknechtschaft," *i.e.*, for the abolition of "interest slavery."[7] Although this anti-finance capital outlook is significant, care must be taken not to identify the liberal, humanitarian premises of Gesell's program with the fundamentally different totalitarian premises of the Nazi party.

In order to explain how unemployment, crises and unearned income could be remedied, Gesell employs a threefold classification of interest rates: the basic rate (a theoretical rate), the rate of return to real capital (an estimated rate), and the loan rate (a contractual rate). Basic interest is described as a purely monetary phenomenon which has nothing to do with time-preference, waiting, or the so-called "productivity" of capital. It does not represent anything which exists in the real world, or at least there are no direct outward manifestations of its existence. Gesell says, for example, "Basic interest has up to the present escaped observation because it was concealed behind its offspring, ordinary interest upon loan-money. . . . Basic interest is a unique phenomenon which must be considered by itself; it is a fundamental economic conception."[8] Attempts to apply the test of correspondence between the concept "basic interest" and the object signified by it are certain to yield negative results because there is no signification of object. The concept has meaning, but there is no question of its (immediate) truth or falsity. There can be no appeal to facts on this level of analysis.

Gesell attempts to clarify "basic interest" by contrasting it with the "rate of return on real capital," *i.e.*, with the hire price paid to the owners of assets other than money. In comparing this rate with the basic rate, he hastens to add: "We ought to cease designating two such fundamentally different things by the same word, interest."[9] This is the reference of Keynes's statement that Gesell distinguishes clearly between the rate of interest and the marginal efficiency of capital.[10]

This same distinction between basic interest and interest on real capital is also used to contrast the declining rate of return on real capital assets with the constant rate of return on money. In this way Gesell points out that it is the money rate of interest which checks accumulation and impedes production. The accumulation of capital assets in no way reduces the independently determined money rate of interest. On the other hand, the accumulation of capital assets does lower the rate of return on real capital. When the latter falls below the basic (money) rate, accumulation ceases because it is now more profitable to hold money than to invest. This forces those who need money as a medium of exchange to pay the (now) higher basic rate. This basic rate, according to Gesell, corresponds to the "difference of efficiency between

[7] Gottfried Feder, *Hitler's Official Programme* (London: Allen and Unwin, 1934), p. 40.

[8] *Natural Economic Order,* pp. 265-66. Gesell's concept "basic interest" is similar to Keynes's "own-rate" of interest on money. *Cf. General Theory,* chap. 17.

[9] *Natural Economic Order,* p. 263.

[10] *General Theory,* p. 355.

money and the substitutes for money (bills of exchange, barter and primitive production) as media of exchange."[11] If it were not that money has a rate of interest of its own (basic rate), accumulation would continue without interruption and the rate of return on real capital would fall and soon become zero.[12]

Gesell did not contend that the introduction of stamped money would cause interest on loans to disappear immediately.[13] His explanation of this is facilitated by the distinction between loan interest and basic interest. Loan interest is used in the ordinary sense, referring to the amount of money paid by borrowers to the lenders of liquid funds. According to Gesell, the loan rate must always equal the rate of return on real capital assets, whether the loan be made in conventional money or stamped money. Loans contracted in stamped money will bear (loan) interest as long as the demand for loan capital exceeds the supply at a zero loan rate.[14] A zero loan rate must await the day when unimpeded accumulation causes capital assets to lose their scarcity value.

In saying that basic interest would disappear with the introduction of stamped money, Gesell means that the consequences which flow from the use of conventional money would be eliminated and processes set in motion which *in time* would reduce the loan rate and the real rate to zero. When this has come about, interest income will disappear, and *rentier* capitalism will be at an end.

In this respect Gesell's ideas on long-run social reform are closely analogous to Keynes's "euthanasia of the *rentier*."[15] The secular decline in the marginal efficiency of capital is another expression for Gesell's long-term reduction in the rate of return on real capital. Keynes tells us he believes that, within a period of a generation or two, unchecked accumulation would make capital assets so abundant that they would cease to yield a return in excess of their cost.[16] Both Keynes and Gesell maintain that pure interest can be made to disappear without socializing the instruments of production. In the new society individuals would still be free to accumulate, but their wealth would not grow automatically through interest accruals. Nevertheless, skilled risk takers would be free to venture their capital in new and uncertain enterprises, and if successful, would get a return in excess of their original investments. Thus the advantages of individual initiative and enterprise would be retained, while nonfunctional income and other undesirable features of the capitalist system would disappear.

The immediately significant difference arising from the substitution of stamped money for conventional forms is that all resources would be continuously employed. Basic interest would not exist as a barrier frustrating new capital formation. The "natural" forces of competitive production would adjust to a level of output at which resources would be fully employed. This

is the meaning, in terms of practical consequences, of Gesell's distinction between basic and loan interest.

Thus, the peculiarity of Gesell's position as a theorist is to be discovered in his attitude toward social reform. Only by referring to his general position as a reformer can his theory be understood. The leading concept, basic interest, takes on meaning in terms of the modified behavior of the economic system which Gesell anticipated would follow from the introduction of stamped money. In some important respects his analysis is not fully developed, but in general the pattern is clear. Gesell's theory is primarily an argument for his program.

War Financing and the Distribution of Income[1]

It is commonly asserted that one advantage of borrowing over taxation in the present juncture is that taxes enacted now will distribute the burden less equitably than would later peacetime taxes collected to pay off the bonds.[2] This assertion does not seem to me at all to reach the real issues involved. It has little relevance for the distribution of the *current* war burden, and it seems as likely as not to be incorrect in viewing the distribution of income by classes over time.

It is surely well established by now, though unfortunately not yet recognized by some of our congressional leaders, that the burden of the present war effort cannot be sloughed off by this generation onto later ones, by borrowing or otherwise. Thus the argument that future peacetime taxes may be more equitably allocated than present ones is largely irrelevant for discussion of an equitable distribution of the current war burden, even assuming that future taxes actually can be more equitably distributed (which is far from certain). In considering the allocation of the burden of war financing, the real comparison must be between the distribution of the tax burden now and the bond burden now (*including the price inflation which will probably come with borrowing*), rather than between present and future taxes. And if it is true that the very low income groups lose especially from inflation—and there is considerable truth in the statement—then even the fact that the rich buy the bonds does not necessarily mean a more equitable distribution of the present burden through borrowing, since borrowing from the rich is especially likely to draw on otherwise "idle" funds and speed price inflation.

The question of the relationship of war financing and income distribution over time (as distinct from the distribution of the war burden) is a much more subtle one than has been generally recognized. It is by no means clear that the low income groups are better off if we borrow now than if we tax, *even though future taxes are assumed to be more progressive than present ones*

[1] I am indebted to Dr. R. A. Musgrave for suggestions and criticisms on this note.

[2] See, for example, J. P. Wernette, "Financing the Defense Program," *Am. Econ. Rev.*, Dec., 1941, p. 761. In accordance with common practice, I shall take "equity" to mean roughly a progressively heavier burden relative to income going up the income scale.

would be.[3] Three simple cases, depending on the type of borrowing and the taxes displaced, may elucidate this point. In these cases by "progressive borrowing" I shall mean borrowing primarily from the higher income groups and by "regressive borrowing" that which comes more than proportionately from the lower income groups, to correspond with the tax terminology in describing revenue sources. In all cases, the assumption that future taxes are more progressive than present ones is accepted. For the moment it is convenient to abstract from the question of individual time preferences.

Case I. In the first case, let us assume that the present borrowing is regressive (perhaps compulsory along Keynes plan lines), and that such borrowing is an alternative to regressive taxation. In this case, the low income groups appear to be better off with borrowing now, since with borrowing they have a claim in a future period on bond redemption income which by assumption will be raised by more progressive taxes. However, a given amount of compulsory saving will almost certainly reduce consumer spending less than the same amount of taxes. Therefore, with the present large inflationary "gap," more price inflation may be expected under borrowing than under corresponding taxes; and, to the extent the lower income groups lose relative to other groups from inflation, any possible long-period gain to them from borrowing is thereby reduced or eliminated.

Case II. In the second and probably more likely case, let us assume that the present borrowing is progressive, and that such borrowing is an alternative to regressive taxation. It is useful to subdivide this case, depending on whether the progressive borrowing correspondingly reduces private spending or comes out of "idle funds."

(a) If the progressive borrowing correspondingly reduces the spending of the lenders, it is approximately as noninflationary as taxes. In this case the low income groups will be better off with present borrowing so long as future taxes are more progressive than those at present would have been if used.

(b) But if, as seems far more likely, the progressive borrowing fails to reduce correspondingly the spending of the lenders, the borrowing is inflationary, and the question of the present redistribution of income and the allocation of the war burden becomes a highly complex one. In judging the effects on the low income groups over time, the question is then whether the future tax system is sufficiently more progressive than the present would have been to more than offset the special losses which major elements of the lowest income groups suffer through inflation. The answer in this case is uncertain; quite possibly the lowest income groups would be worse off with present inflationary borrowing than with present regressive taxes.

Case III. In the third case, let us assume that the present borrowing is progressive, and that such borrowing is an alternative to progressive taxation. In this case the low income groups are clearly worse off under borrowing, unless it be assumed that future taxes to pay off the debt will be even more progressive than those at present would have been if used. This conclusion holds even under the assumption that the present progressive borrowing is non-

[3] If the contrary assumption is made, obviously the basis for the argument under discussion vanishes.

inflationary. If the present borrowing is inflationary, as is more likely to be the case, the likelihood of loss to the lowest income groups is correspondingly increased, as noted under Case II (b).

The introduction of time preferences complicates the matter further. Whether one should assume it is more important for a poor man to have a dollar now as compared to the future than for a rich man is not clear. The answer depends not only on personal preferences (where the poor probably place more emphasis on present income), but also on the absolute level of national real income and its distribution.

A Note on Price Discrimination in Steel

In *Price Discrimination in Steel* (T.N.E.C. Monograph No. 41) it is argued that the steel industry offers very large quantity discounts to the buyers of its products. From this statistical conclusion the authors make numerous inferences, among them that the competitive position of small buyers of steel is endangered and that the federal government pays too much for steel (p. 27). These inferences may be true, but this note attempts to show that the statistics on which they rest are quite unsatisfactory.

The basic data consist of prices and freight charges (actual and charged) on various steel products by size of shipment, in February, 1939. These data are converted to a per ton basis and then summarized by classes. The most striking case is reproduced in the table below as an illustration of the results. The authors conclude that "the price concessions to the big [automobile company] buyers can be seen to be very substantial" (p. 23).

PRICE OF COLD-ROLLED STRIP[a]

Size of Shipment (in tons)	Mill Net	Net Extras	Base Price
Under 3	$138.63	$73.21	$66.51
3 to 10	145.41	72.21	74.37
10 to 30	104.84	45.77	60.25
30 to 100	92.67	32.64	60.78
100 to 300	92.23	34.27	58.51
300 to 1,000	70.88	11.14	59.55

[a] Taken from T.N.E.C. monog no. 41, p. 23.

There is one basic defect in the procedure. The "extras" explain almost all of the difference in the mill net receipts. These "extras" were actual charges, not quoted prices. It is impossible to discover from the monograph whether the decline in charges for "extras" as size of shipment increases is due to lower quoted prices or to reductions from quoted prices secured by bargaining power. Moreover, if this separation were made, it would be impossible for the non-expert to decide which of the two, actual or quoted prices, was more

appropriate to the cost differentials of the "extras." If the "extras" were charged at rates justifiable on cost grounds, there was little discrimination in the pricing of steel. Subtracting "extras" from mill net leaves a mill net for products of standard specification which falls from $65.42 to $59.74, or about 9 per cent, and not the 50 per cent suggested by the mill net figures. This 9 per cent decline could also be due to cost differentials, of course.

The authors meet this point by saying that "quality demands on large orders are frequently very exacting" (p. 23). If this comment is not irrelevant it implies that the charges for "extras" are not proportional to their costs. Since this is a crucial question in the interpretation of the statistics, it would have been reassuring to support it with evidence.

The Economists' Tariff Protest of 1930

The economists' statement in opposition to the Hawley-Smoot tariff bill was a unique document. No pronouncement by American economists has ever attracted the public attention that this received. It seems desirable, while memories are reasonably accurate and some of the correspondence relating thereto is still available, to give a brief history of this protest. Since my friend, Professor Clair Wilcox of Swarthmore, who was the leading spirit in the matter, declines to tell the story, I take the liberty of doing so.

With the sharp division of economic opinion in recent years on so many issues of public policy, it is hard today to realize the almost unanimous opposition of economists, in the spring of 1930, to the tariff bill then pending in Congress. Economic faculties that within a few years were to be split wide open on monetary policy, deficit finance, and the problem of big business, were practically at one in their belief that the Hawley-Smoot bill was an iniquitous piece of legislation. What later developed into a statement backed by over 1,250 economists originated in a very modest way out of the desire of Wilcox and some of his associates at Swarthmore to voice their protest. At the suggestion of Wilcox, Professor Paul Douglas of the University of Chicago, who was then temporarily at Swarthmore, drafted a statement in March that, with some changes in phraseology, was the one given to the press five weeks later. It was decided to ask an economist at each of various eastern universities to sponsor the statement, and then to send it to a member of the economics faculty at each American college, with the request that he solicit signatures from his colleagues. Professors E. M. Patterson of Pennsylvania, Frank D. Graham of Princeton, Henry Seager of Columbia, Irving Fisher of Yale, and F. W. Taussig of Harvard, were asked to join Wilcox and Douglas in sponsoring the statement. This they all agreed to do. As a result of the comments of these men a few changes were made in the text, and at the suggestion of Fisher a paragraph was added pointing out the significance of tariff policy in connection with America's creditor position.

Fisher also made the suggestion that the entire membership of the American

Economic Association be circularized, and offered to pay the difference between the cost of this and the estimated cost of the original plan. This was done at a total cost of $137, of which Fisher contributed $105. With the clerical assistance of Swarthmore students, the statement was sent out to over 2,500 members of the American Economic Association with a request for signatures. The response was an amazing one. Inside of ten days nearly a thousand signatures had come in, including those of most of the leading figures in American economics. What had started on a simple scale had snowballed into what promised to be a document of national significance.

Wilcox delivered a copy of the text and signatures to President Hoover, Senator Smoot and Congressman Hawley, and gave the material to the press in Washington for release on Monday, May 3. Political opponents of the bill and newspapermen who sensed the news value of the statement took care of the publicity. Senator Pat Harrison had the statement and the list of signers read into the *Congressional Record* of May 5.

Veteran newspapermen, to whom the nation-wide attention that the statement received seemed to indicate a high-powered publicity campaign, backed by ample appropriations, were almost incredulous when they learned that the protest had been organized and carried through at an expense of less than $140. This was possible only because of a virtual unanimity of economic opinion on an important issue and the release of the statement to the press at a particularly opportune moment.

Correction

An obviously erroneous statement appears in my recent article, "Tax Shifting in the Market Period," in the *American Economic Review* for March, 1942. The error fortunately does not affect the validity of any of my arguments or conclusions. The incorrect statement appears on the lower half of page 74. It runs as follows: "It is a familiar fact that under both pure and monopolistic competition the individual seller is in market equilibrium when his reservation price is equal to marginal revenue." The statement is correct in the case of pure competition but incorrect in the case of monopolistic competition.

BOOK REVIEWS

Economic Theory; General Works

The Theory of Consumer's Demand. By RUBY TURNER NORRIS. (New Haven: Yale Univ. Press. 1941. Pp. 220. $3.00.)

The recognition of the phenomenon of product differentiation, and its explicit introduction into economic theory, has wrought a substantial change in modern price and market analysis. So far, however, only those implications of differentiation which affect the conditions of supply have been thoroughly explored; it remains to consider its implications for the theory of consumers' choice. It is to the rewriting of the latter theory subject to the assumption of ubiquitous differentiation of products that *The Theory of Consumer's Demand* is primarily devoted.

The book, involving as well a general critique of the theory of choice as it has come to us from the Austrians, from Walras, from Marshall, and more lately from Hicks, is divided into two main parts. The first of these, preparatory to the main thesis, is a straight-forward exposition and evaluation of the indifference curve analysis recently popularized by Hicks. This presentation is wholly in geometric, arithmetic, and literary terms, and serves as a good interpretation of Hicks for the nonmathematical reader. Hicks's principal conceptions of substitutability, complementarity, etc., are investigated; his basic assumptions are explored; and the indifference and marginal utility analyses are carefully compared. While the contribution of this section is largely expository and critical, it should be particularly useful as an introduction for graduate students to the ideas of Mr. Hicks.

The second and principal section is devoted primarily to a theory of choice and demand in terms of related goods or differentiated products. The theory involves the development of three main, related propositions. Of these the first is that people's consumption habits are such that they never consider their expenditure patterns in a "general equilibrium" sense; that all problems of choice are necessarily "partial equilibrium" in character; and that therefore a realistic theory of choice should be primarily concerned with partial rather than with general equilibrium problems of choice. Rejecting the idea of a highly hedonistic individual, the author argues that the individual's consumption pattern is derived not from a conscious calculus of choice among all the items in his budget, but rather from his cultural heritage. This inherited budget pattern is conventional, inflexible, and changes only slowly. Such deliberate changes as are made affect only a limited area of consumption, and are necessarily successive rather than simultaneous. Hence the necessity of shifting theoretical emphasis from the general to the partial equilibrium type of choice decision.

The second main proposition is that the sort of theory of choice indicated

needs first to be differentiated into a long-run and short-run theory, a conspicuous omission on the part of contemporary writers. To this end the author develops first a short-run theory of demand, concerning consumer response to price changes in "a period of time so short that no changes in income and *no changes in established consumption rates*[1] occur." In such a period consumer reactions to price change consist of the hoarding or dishoarding of money, the building up or depletion of stocks of goods, and experimental purchases on items outside the normal budget. Previous commitments have a rigidifying effect on the expenditure pattern, and calculations of marginal utility (or of marginal rates of substitution) have no valid application. The author holds that the short-run theory of demand is particularly distinct from the long-run for the great mass of differentiated, non-staple products which are particularly likely to be stocked in response to price changes, and for "petty goods" purchased experimentally in the short run. Although such a theory is suggested rather than fully developed, the suggestions are penetrating.

The third main proposition is that the basic (long-run) theory of choice must be rewritten to emphasize the primacy of partial equilibrium choices within groups of close substitute, differentiated products. A simple non-mathematical theory is developed along this line, and recognizes two main categories of differentiated groups. The first includes groups of out-and-out substitutes, within which the consumer makes a choice, as, for example, among various makes of automobiles. The discussion of this problem, emphasizing the phenomenon of a single choice from multiple alternatives variously priced, is well handled. The second category of groups is that of complementary substitutes, an innovation of the author. Complementary substitutes are groups of differentiated goods each member of which is specialized to a particular subdivision of a general want—as, for example, tennis shoes, walking shoes, and dress shoes—and which have an aggregate utility when possessed in groups greater than the sum of individual utilities when possessed separately. The establishment of this category is obviously no mere terminological innovation, but a recognition of a real phenomenon heretofore largely neglected. For such goods, which the author believes to be a dominant category, she devises an appropriate theory of choice.

In sum, therefore, what is suggested and developed is a major shift in emphasis in the theory of consumer choice toward choices by the consumer among clusters of competing substitutes and complementary substitutes, as they arise out of the ubiquitous phenomenon of product differentiation. This work constitutes a definite contribution to the theory involved, not primarily on the technical level, as it is argued largely in terms of arithmetic and geometric examples and never in a highly general form, but rather on the level of a revision of basic assumptions and of an exploration of the general implications of these revisions. The major propositions concerning human psychology and habit and concerning the occurrence of products in differentiated clusters are smoothly fused into a consistent major argument.

A final aspect of the work involves some suggestions concerning the impli-

[1] Italics mine.

cations of the modified theory of choice for the demand curves of the sellers of differentiated products. The phenomenon of discontinuity of demand curves at conventional prices, the effect of an increase in the number of products in a cluster on the elasticity of demand for each of them, and other issues raised in recent price literature are discussed, although this treatment does not progress far beyond the expository level. This portion of the work suffers from a limitation common to a considerable portion of literature in the Chamberlinian tradition (not implicit in Chamberlin's own work)—a preponderant emphasis upon the effect of product differentiation on the demand for the individual seller, and an insufficient emphasis on the importance of fewness of sellers within a "cluster."

It would have been appropriate if this highly realistic treatment of consumer choice could have been capped by an equally realistic explicit recognition of the fact that in modern markets pure oligopoly and especially differentiated oligopoly, as opposed to monopolistic competition in the sense of product differentiation plus large numbers, are the dominant categories. All cases of markets involving large numbers are peripheral to these dominant categories in the same sense that the author holds unrelated homogeneous goods like wheat and cotton to be peripheral to the dominant clusters of complementary substitutes. The various subdivisions of the oligopoly category should be explicitly the concern of such a work as this in so far as it touches on sellers' demand.

This limitation, however, in no way affects the substantial merit and novelty of the bulk of the work, which is concerned primarily with the theory of consumer choice. On this level the author has made a substantial contribution to contemporary theory.

JOE S. BAIN

A Theoretical Analysis of Imperfect Competition with Special Application to the Agricultural Industries. By WILLIAM H. NICHOLLS. (Ames: Iowa State Coll. Press. 1941. Pp. xiv, 384. $3.75.)

This excellent volume is addressed primarily to the large body of agricultural economists. It should, however, prove useful not only to the specialists but also to most economic students who will find in it an extremely readable review of a large sector of current economic theory.

The title is indicative of the dual nature of the book's contents. It is chiefly a theoretical study, but it contains at the same time a great deal of empirical material about agricultural processing and distributing industries. Dr. Nicholls has tried to achieve two goals. First of all, he attempts to demonstrate that agriculture is not, as is so often implied, a sort of sanctuary for the theorists of pure competition. The processing agricultural industries must be studied in terms not of pure, but of monopolistic competition. As it now stands, however, the analysis of imperfect competition may be too complex or ill adapted for practical use in agricultural research. Dr. Nicholls has also set about to remedy these defects.

The small scale of farming operations coupled with the relatively standardized nature of their products appears, at first glance, to fulfill the strictest requirements of purely competitive theory. This is not so, however, for the buying side of the market does not conform to the necessary assumption of atomistic behavior. The three largest buying firms of livestock account for 57 per cent of the total volume handled; the percentage is 46 per cent for tobacco leaf, 38 per cent for wheat, 30 per cent for canned vegetables, 21 per cent for milk. Pure competition among sellers is matched with oligopsony, not pure competition, among buyers. These departures from purely competitive standards are further enhanced by the geographical barriers between local submarkets. What is needed by the agricultural economist, therefore, is a thorough understanding of imperfect competition among buyers and, especially, of the nature and functioning of oligopsonistic markets. Since imperfect competition has been developed mainly with reference to the selling side of the market, the first task is to reinterpret it in terms of imperfections in the buyers' market. Dr. Nicholls's book is largely devoted to the problem of putting into reverse gear the familiar Chamberlinian analysis of monopolistic competition. In a good two hundred and fifty pages he discusses, from this point of view, the various cases of monopoly-monopsony, oligopoly-oligopsony, bilateral monopoly, service and product differentiation, and price discrimination.

The theoretical problem is handled skillfully and in a very readable form. Dr. Nicholls disclaims any ambition to be a "tool-maker" and clings tenaciously to the useful, if ungrateful, task of a "tool-adapter." I cannot help feeling, however, that he is, at time, somewhat too faithful to his models. Although he recognizes explicitly the limitations of particular equilibrium methodology, he makes no effort to escape its fetters and the analysis runs, throughout, in Chamberlinian and Robinsonian terms. The discussion of derived demand, in Chapter 2, would have gained enormously if the now familiar tools of indifference analysis had been resorted to. Only in this way is it possible to make any sense out of the concept of the elasticity of substitution. As used by Mrs. Robinson and Dr. Nicholls, the "elasticity of substitution" is a mere rechristening of the problem which confronts us. It does not bring its solution one step nearer.

The otherwise excellent discussion of oligopoly-oligopsony suffers from a certain hesitancy, on Dr. Nicholls's part, to choose between pure and applied theory. The first half of the analysis is little more than a rehash of Chamberlin's Chapter 3 with hardly any relevance to real agricultural markets. (Incidentally, Dr. Nicholls seems to identify Bertrand's and Edgeworth's solutions of oligopoly. Edgeworth's solution, although starting from Bertrand's model, introduces highly restricted assumptions and concludes that the price will oscillate between the monopolistic and the competitive level, while Bertrand argued that the equilibrium price would be the same as under pure competition. Dr. Nicholls's objections apply to Edgeworth's scheme rather than to Bertrand's.)

The discussion begins to be interesting when Dr. Nicholls takes leave of his authorities and investigates the more realistic situations where one or a few

firms dominate the market. The argument explaining how, under such conditions, the influence of entry is likely to bring about competitive profits, but with excess capacity rather than with competitive prices, is a model of clarity. On the other hand, his assertion that where a few firms dominate the market, we should expect "that prices throughout the industry would tend to be established at such a level as to maximize the profits of the most efficient of the dominant firms" because ". . . in their relationship to each other, a few dominant firms must recognize the most efficient of their number as their leader" (p. 143) seems to me rather gratuitous. Larger size, or superior financial and research means, may—"regardless of efficiency"—be the decisive factor in enforcing leadership among the dominant firms as well as between the dominant firms and the others. In the steel industry, for instance, is the U.S. Steel Corporation the most efficient of the dominant firms?

The section on price discrimination includes a brief discussion of empirical supply and demand curves. I doubt whether this will be of much help to most readers. A disproportionate emphasis is placed on the influence of time-lags upon the shape of the curves, but other fundamental difficulties are hardly touched upon. Indeed, outside of pure competition, it is difficult to give any precise meaning to industrial demand and supply curves. Moreover, would not the supply of many agricultural products depend, not so much on their own prices in isolation, but rather on the relation between that price and the prices of other agricultural commodities to which production might be shifted? Nor does Dr. Nicholls discuss the primary statistical problem of isolating shifts of demand from shifts of supply. I think it significant that, in recent years, the attention has shifted largely from the study of statistical *supply* curves to the investigation of statistical *cost* curves.

Having shown the pervasive influence of monopsonistic factors in agricultural markets, Dr. Nicholls sets about answering a second objection to the extension of imperfect competition analysis to the agricultural field. "The fact that processor-distributors do not directly control the short-run supply of the farm product has . . . frequently been interpreted as precluding the existence of imperfect competition among them" (p. 1). "The natural reaction . . . is that, since there is no control over the supply (hence none over price), there can be no monopoly" (p. 353). Dr. Nicholls points out that this lack of control over the short-run supply of farm products is not relevant to the position of the processor. The latter's monopoly rests upon the control, not of the farm product, but of his processing-distributing services and of their price, *i.e.*, of the spread between the price paid to the farmers and the price received for the processed product. Concentration of control among the processors-distributors need not, however, result in constant spreads. If the dominant firms were able to forecast future supplies accurately, imperfect competition would, just as pure competition, lead to relatively flexible margins. Margin inflexibility should be associated, not with mere concentration of control, but with the uncertainty of the dominant firms as to the responses of producers and consumers to price changes. Personally, I would stress as equally important the uncertainty of each processor as to the reactions of his rivals, and the resulting tendency to price—or, in this case, to margin—stickiness. Finally, it is re-

marked again that in so far as the control of competition and entry is imperfect, profits may fall to the competitive level while the margins remain high, due to the wastes and costs of excess capacity.

This brief summary does not do justice to the book. Dr. Nicholls has made excellent use of his empirical data in illustrating the theoretical analysis. This close interpenetration of theory and facts is, to me, the most valuable part of his work. Those who are looking for an agricultural Burns's *Decline of Competition* will only regret that he did not do more in this direction. Indeed, outside of meat packing and milk marketing the empirical material is rather scanty and comes in mainly by way of examples. In view, however, of the difficulty of the task and of the limitations of space, Dr. Nicholls should be commended for what he did, rather than blamed for what he has not yet done.

My main criticism would rather be directed toward his heavy reliance on a few standard works in the fields which he covers. This is especially apparent in his discussion of economic dynamics and in his treatment of oligopoly. With relation to the latter, the literature reviewed is nearly exclusively Chamberlinian, and no mention is even made of such names as Kahn, Sweezy, Smithies, etc. As a result, the solutions offered are unnecessarily narrow and arbitrary. To a certain extent, this is, of course, unavoidable in dealing with a problem which admits of an infinity of solutions. Much could have been gained, however, by shortening the discussion of the traditional Cournot-Edgeworth controversy, and devoting some attention to more significant models such as cut-throat competition, price stickiness, etc.

As it is, though, Dr. Nicholls has performed brilliantly a most useful service. He has disposed very effectively of the old shibboleth that imperfect competition is inapplicable to the agricultural field. In addition, he has retooled many of the current weapons of monopolistic competition and short-run dynamics in such a way as to simplify their mastery and to adapt them for ready use in the study of agricultural markets. The readers of the present volume will undoubtedly await with high expectations the future writings, alluded to in the Preface, in which Dr. Nicholls will apply his own theorizing to further problems of practical research.

ROBERT TRIFFIN

Harvard University

Introduction to Responsible Citizenship. By WILLIAM E. MOSHER and Associates. (New York: Holt. 1941. Pp. viii, 886. $3.25.)

Responsible Citizenship is designed as a textbook for an introductory course in social science or human relations. This intent should not blind one to the fact that it can also serve as a highly literate survey for the mature scholar who wishes to sink his teeth into an exercise in perspective and synthesis. The contents represent the equilibrium attained by the faculty of the Maxwell School of Citizenship of Syracuse University after some sixteen years of experiment with various subject matters. The reviewer knows from personal experience the extent to which the detail has been hammered out and

constantly revised in weekly conferences of the representatives of the various social sciences who have shared in the teaching.

The book is a compromise between the compartmentalized, capsule survey course in the social sciences and the integrated fusion course in social science. It starts bravely as a general study of human behavior grounded in social psychology and expressing itself in various aspects of life. This view of social behavior in general is followed by a survey of its peculiar expression in governance. However, the behavioristic approach is almost totally absent in the subsequent treatment of economics and is muted in the history of democracy which follows the economic section. It is again resumed in Part V, under the title "Rival Social Philosophies."

All textbooks and courses aim to promote understanding and social insight, and this is no exception. On the other hand, this particular book belongs to the minority which have the courage explicitly as well as implicitly to motivate their readers toward a given course of social action. With all their hearts, the authors favor the democratic, positive state, and raise alternatives largely to refute them. It is, however, no paternal bureaucracy which is the authors' utopia. At every point the student is exhorted himself to participate in democratic activity, and arguments therefore are given in full. The title is well chosen.

Dean Mosher opens the book with a reasoned essay on the meaning and challenge of responsible citizenship in contemporary society. This is followed by Professor Haring's section on "Social Behavior." In this section, the fundamentals of social psychology are outlined and their expression in society indicated. The Iroquois and Japanese cultures are used as examples, with the obvious and successful intent of leading the student to see institutions in his own culture, not as permanent and God-given, but as the product of time and place. The parts of this section which deal with cultural analysis are better done than those concerned with social psychology. One suspects that the author's desire not to be vulnerable to criticism from the profession may have made him reluctant to commit his views to print with that clarity and precision which is desirable in an introductory course. The result has been a certain blurring in the subject matter.

Professor Beyle's section on "Governance" is clear and interesting, and makes full use of the approaches of the earlier portions. It is abstract in its premises and conclusions, but each abstraction is buttressed by a wealth of concrete illustrations drawn in many instances from the experience of university students. Government is pictured as social control with an ever-varying range of activities. These activities express themselves through institutions, but the latter are pictured realistically, and not as mystical entities. Issues are treated as the outgrowth of motivational differences, and these are traced to their origins.

The section on economics suffers somewhat from the fact that it is not well integrated with the other parts of the book. Considered as a unit by itself, however, the reviewer has nothing but praise for it. In a scant two hundred pages of clear and interesting writing, Professor Ross has packed all of the main features of contemporary institutional economics. By the author's device

of constantly raising questions the student is or should be safeguarded from the temptation of superficiality. The major issues raised include capital formation, monetary control, cyclical variations, capacity for production, state control, and remedies for maldistribution, exploitation, and unemployment.

Professors Galpin, Harlow, and Mosher share the responsibility for Part IV, which in effect is a history of democracy. The contributions of Greece, Rome, the Renaissance and Reformation, the American and French Revolutions, Jefferson and Jackson, and the Progressive Movement are passed in review. The material is compact and closely knit. It succeeds in illuminating the democratic way as cumulative and ever-developing.

The final section treats democracy, communism, and fascism as alternative ways of life. Considering the magnitude of the respective subjects—each assigned but a chapter—a reasonably clear and objective picture emerges. The picture occasionally sacrifices accuracy to the necessity for a measure of oversimplification; and omits altogether certain important aspects, such as the corporatism usually associated with fascism. The contrast between theory and practice in communism is well brought out by Mrs. Fisher, as are also the similarities and differences between communism and fascism. Dr. Mosher contributes the conclusion, which restates the introduction in the light of what has gone between.

In a work purporting to cover the whole field of human relations, a reviewer is almost certain to look for more than it is humanly possible to cover. Nevertheless, the work is not merely a study of democracy, but it is also a tract urging its preservation. Hence one would expect to find pointed out in the contemporary scene the connection between religions which hold the individual sacred and the preservation of human rights. Instead there is a studied avoidance of this approach, and individual rights are discussed either as merely expedient or at the most as in some fashion biologically grounded. Moreover, Professor Haring seriously weakens even this approach when he assumes (p. 172) that democracies are inefficient as compared to dictatorships and tyrannies. However, criticisms of this sort must not obscure the fact that the work succeeds in its avowed purpose. My recollection is that for a number of years the course on which this book was based was consistently voted the "most valuable" by a majority of the students taking it.

Washington, D.C.

Economic History

Burlington West, A Colonization History of the Burlington Railroad. By RICHARD C. OVERTON. (Cambridge: Harvard Univ. Press. 1941. Pp. xviii, 583. $4.50.)

Mr. Overton's study, following the pioneer researches of James B. Hedges for the Northern Pacific and the Canadian Pacific and of Paul W. Gates for the Illinois Central, deals with the organization, methods, and results of the

colonizing activities of the Burlington and Missouri River Railroad. The sources are so abundant that they have provided almost an embarrassment of riches. The records of the land department in the Baker Library at Harvard are supplemented by the official records and archives of the road, various collections of correspondence, public documents, newspapers, and local histories. The only potentially important sources not utilized are German and Scandinavian newspapers published in the United States. The bibliography is too inclusive and indiscriminative. Superficial popular books that can contribute nothing to the subject are included with works of original scholarship, and thirteen textbooks, including one of high-school grade, are listed. The narrative is generously documented and embellished by quotations, pictures, maps, and graphs, and supplemented by an extended documentary and statistical Appendix.

Mr. Overton's historical contribution would have been increased by greater unity of treatment. In the possession of such ample stores of interesting and often highly picturesque material, he is led to turn aside from his monographic labor to consider collateral topics and colorful episodes not pertinent to his theme. Background details, legislative and administrative policies, and descriptions of changing types of rolling stock—however significant and interesting in themselves—could well have been compressed or omitted for the purposes of this study.

The slips and omissions that have been noted are due mainly to carelessness in checking background facts and local details. William J. Sparks was Commissioner of the General Land Office not "Secretary of the Interior." The same James Harlan is given two separate entries in the Index as Secretary of the Interior and Senator. The noted Massachusetts lawyer "Edward R. Hoar" obviously refers to E[benezer] Rockwood Hoar. James Thorington, the first free-soil member of Congress from Iowa, should be mentioned in connection with the railroad land-grant of 1856, for which he received contemporary credit and discredit. Fairfield, Iowa, is in Jefferson not "Henry" County. Experience has not shown that the dry-farming system of Hardy W. Campbell has been "very satisfactory." The extension activities of the Burlington described in the concluding chapter should not be confused with colonization policies.

The author makes an obvious effort to maintain a judicial attitude but he does not disguise his feeling that the historians have overemphasized the gains and underrated the services of the railroads in the disposal of their lands. With the full record at hand, the case is strongly presented for this particular road.

The Burlington was no doubt somewhat exceptional in the standard of its leadership and in its foresighted and enlightened policies in dealing with settlers. None the less the road and its officials were not apart from their time and its business methods. Threatened repudiation to force a certain class of bondholders to convert presses hard the general interest argument. The manipulations of "town site companies" of railroad officials is too easily justified as a safeguard against irresponsible speculation. The extensive intermingling of church and denominational college establishment with settlement

promotions often conducted by ministers, as well as the subsidizing of clergymen and "professors" for various types of "oblique advertising," suggests the curious interrelations of God and mammon characteristic of Jay Cooke. But it should be said for the Burlington associates that their frankly avowed motive was always that of straight business. Incidentally, the opinion held at the time and since that certain Secretaries of the Interior were, for whatever reasons, partial to the claims of the railroads is given considerable justification by the rulings here recorded.

Of necessity the roads followed much the same techniques and practices; they were all a part of the "system" which was often one of trial and error. The B. and M. drew on the experiences of the Illinois Central and even more directly of the Hannibal and St. Joseph and frequent interchange of officials tended to standardize organization and methods.

Considering the limitations, public and private, under which the companies operated, definite conclusions as to relative "soundness" and expediency of particular policies are difficult to reach. What does stand out, in this as in other policies of land disposal, is the lack of definite information and reasoned plan by the government, the corporations, and the settlers. Mr. Overton observes that the question as to whether the development of the country in this way was premature is beyond the scope of his investigation—but it is an issue that cannot be ignored by the student of the economic and social history of the nation.

Economic Systems; National Economies

Russia's Economic Front for War and Peace, An Appraisal of the Three Five-year Plans. By A. YUGOW. Translated by N. I. and M. STONE. (New York: Harper. 1942. Pp. ix, 279. $3.00.)

In spite of a large number of books, pamphlets and articles on various aspects of the Russian development which have appeared since the outbreak of the Russian-German war, there has been no serious publication dealing with the economic problems of the Soviet Union. This gap has now been filled in a very satisfactory fashion by the appearance of the excellent study by Dr. Yugow. Although a political emigré—he is one of the foremost leaders of the Russian Social-Democratic Party (Mensheviki) which has been suppressed in the Soviet Union ever since the early twenties—the author was able to present a highly objective and unbiased history of the three five-year plans. The volume acquaints the reader with all the salient facts in the field of Soviet economics and thus provides a handbook which is particularly valuable at the present time.

The handbook character of this work, however, is responsible for some of its shortcomings. The treatment of the vast subject is organized in a rather infelicitous manner, and the individual chapters—dealing with industrializa-

tion, agriculture, internal commerce, foreign trade, finances, and so forth—tend sometimes to become repetitive and a little dreary. It is a pity, furthermore, that the author never refers to any writings except the ones in Russian, and it certainly would increase the usefulness of the book if its second edition included a bibliography comprising publications in the English language which—whatever their value—are more easily accessible to the reader in this country. Moreover, taking into account and discussing such non-Russian work (*e.g.*, Colin Clark, Dobb, Reddaway, Hubbard, the articles of Chossudovsky in the *Review of Economic Studies,* etc.) would have induced Dr. Yugow to broaden the scope of his investigations and to pay more attention to some theoretical issues which are of considerable interest to the non-Russian economist.

For example, the problems arising in connection with the determination of the size of the national income in an economy in which prices are fixed and goods allocated by a planning authority are not even mentioned by Dr. Yugow. Nevertheless, he uses the figures referring to the changes of the national income and hardly ever questions their significance.

In the same, rather uncritical way he speaks frequently about costs. "The cost of production in Soviet industry is much higher than that of foreign countries or of Russia before the First World War" (p. 39). If it is money cost which he has in mind, then everything would depend on the way in which he evaluates the Soviet ruble in terms either of the Czarist ruble or in terms of a foreign currency. As such a unique relationship between Soviet money and other exchanges certainly does and did not exist, and as the expression "ruble" has in reality always been an abbreviation for quite a number of legal tenders of different purchasing power (depending on the station in life of its possessor, the rations which he was entitled to claim, etc.), it appears doubtful whether it is useful to compare costs in the Soviet economy in monetary terms either with the pre-war costs in Russia or with costs abroad. The comparison would appear somewhat more justified, if the "real costs" (in the Marshallian sense) could be studied and confronted with "real costs" in other countries. But Dr. Yugow does not and presumably could not do this, as data on "real costs" are not easily construed, especially not for Russia.

Speaking of the turnover tax which plays a very significant part in Russian public finance, Dr. Yugow remarks that this tax is highly anti-social (p. 132). That is true, however, only if the inequality of income is very great. He believes, indeed, that such is the case (p. 258) but hardly tries to prove this contention. The degree of inequality and how it compares with other countries could be measured with the techniques of the Pareto or Lorenz curves, but such a research has—to this reviewer's knowledge—never been undertaken[1] and it appears rather uncertain whether it would yield meaningful results corroborating Dr. Yugow's opinion.

But all these more or less important drawbacks are fully compensated by the admirable clarity with which Dr. Yugow analyzes the main issues of the

[1] With the exception of a doctoral dissertation of A. Bergson filed at Widener Library (Harvard University) but unfortunately unpublished.

economic policy of the Soviet Union. The decision to devote about half of the national income to investment and armament resulted by necessity in privations to the civilian population. Shortages of all kinds and tremendous difficulties of administration were unavoidable. Disproportionalities in the growth of individual industries, troubles with respect to agriculture, hitches of various importance were the necessary concomitants of the terrific strain to which the economy of a backward country was submitted by political decision. Form and content of planning are interdependent. Planning for abstinence has to resort to different means from planning for welfare. The information which Dr. Yugow supplies shows what could have been accomplished, if houses could have been built instead of tanks and roads instead of fortresses. One can heartily concur with his hopes that after this war the Soviet Union, freed from the permanent threat of invasion, will be able to use the powerful mechanism of rational utilization of resources in order to secure a steady increase of welfare for her population and thus create the all-important condition for the growth of a free and democratic society.

PAUL A. BARAN

Washington, D.C.

Ekonomika Sotzialisticheskoi Promyshlennosti (Economics of Socialist Industry). By E. L. GRANOVSKII and B. L. MARKUS, editors. (Moscow: Akademiya Nauk, Institut Ekonomiki. U.S.S.R. 1940. Pp. 598. 10 rubles.)

This textbook on economics was written by a group of economists connected with the Institute of Economics of the Academy of Science of the U.S.S.R., and is intended for students in institutions of higher learning who already have had some background in economics and the history of national economy.

In the Introduction, the problems and tasks of socialist industry in Soviet Russia are discussed. The chief problems of the economics of socialized industry are those of an increase in the rate of capital accumulation and the development of factors which will bring about a change from socialism to communism. The solution of these problems will require a further extensive development of socialist industry as a whole and of its separate industries. The direction of capital formation is closely related to the selection of the size of industries, specialization and coöperation, combination, location of industries, and allocation of resources. The economics of socialist industry deals also with the most advantageous combination of large, average and small enterprises and relationships between them, as well as the achievement of equilibrium between industry and related fields. Among other tasks of the economics of socialist industry is that of studying the struggle of the party against the restoration of private capitalism, and to "struggle against bourgeois theories and opportunistic distortions in the field of science" (p. 13).

The material of the text is discussed in the following order:

1. Stages in the development of socialist industry.

2. Industrial program of socialist production, dealing with the volume of production; per capita production; comparisons with foreign countries, particularly the United States; the development of new industries; planning of the production program; allocation of resources; and distribution of goods.

3. Development of the technical bases of socialized production, including technical reconstruction and improvements.

4. Concentration, specialization, coöperation, and combination in industries.

5. The geographical location of industries and the distribution of raw materials. This is the most interesting part of the book, from the point of view of the reviewer, since it describes the location of the main industries, the state of their development and plans for their future development.

6. Capital formation in industries, that is, the amount of capital allocated to the development of various industries. The elements composing these funds consist of capital equipment.

7. Basic funds of socialized production. The process of production requires labor and means of production; the latter are the means of labor (capital equipment, buildings, etc.) and objects of labor (raw materials, semi-finished goods, etc.). The methods of valuation used are: (a) cost of production, (b) cost of replacement, and (c) cost less depreciation.

8. Productive capacity of industries, its use and seasonality.

9. Cost of production and quality of production. In the U.S.S.R. "the price of an article does not represent a monetary equivalent of the cost of its manufacture. Price is the basic lever for the redistribution of the national income and is determined in accordance with definite political and economic policies carried on by the Party and Government in relation to the stage of economic development of the U.S.S.R." (p. 498). For instance, before 1936 prices of metal and coal were below cost of production and the difference between cost and price was covered by the state.

10. Finances of socialized production and their control by the state. The sources of funds needed by industry come from: (a) income and savings of these industries, (b) credits granted by the state and industrial banks, (c) grants from the state budget. Part of the surplus realized from the sale of goods by an industry is turned to the state in the form of turnover tax. In 1937, the turnover tax from industry amounted to 60.6 per cent of the total revenue of Soviet Russia. The state bank grants credits only for (a) seasonal needs, (b) goods in transit, (c) temporary needs, and in some cases for capital repair. Credits granted by the bank represented 37.2 per cent of the total turnover funds of the industry on January 1, 1938.

11. The last part is devoted to administration and planning. The plan of every industry is actually a part of one over-all national plan. This planning is performed by several agencies which receive directives from the Central Committee of the Party.

The book contains a large amount of valuable material and statistical information depicting the enormous industrial development of the country within the last decade or so. However, its value is much impaired by criti-

cisms and attempted but impossible comparisons with the economic structure and operations of the capitalist countries.

M. V. CONDOIDE

Ohio State University

Canadian War Economics. By J. F. PARKINSON, editor. (Toronto: Univ. of Toronto Press. 1941. Pp. vii, 191. $1.75.)

This compact and interesting little volume gives us the story of the Canadian war economy through the middle of 1941. Among the contributors are Professor A. F. W. Plumptre (Organizing the Canadian Economy for War); Mr. Henry Borden, general counsel to the Department of Munitions and Supply (The Work of the Department of Munitions and Supply); Mr. J. D. Gibson, editor of the *Review of the Bank of Nova Scotia* (Financing the War); Professor K. W. Taylor, secretary of the Wartime Prices and Trade Board (The Wartime Control of Prices); Mr. B. M. Stewart, deputy minister of the Department of Labour (Wartime Labour Problems); Mr. L. Rasminsky, assistant to the chairman, Foreign Exchange Control Board (Foreign Exchange Control); and Mr. Tom Moore, president of the Trades and Labour Congress of Canada (Organized Labour and the War Economy). It is striking that practical men of business and academic economists coöperated so successfully in this venture. That they did also reminds one of their coöperation in the administration of the current war economy. In the Canadian war economy, however, the business men seem to be in control more than they are on this side of the border.

This volume is of particular interest to Americans because the Canadian war economy's shift to high gear precedes the American shift. We can learn much. As Professor Plumptre points out in his excellent introductory chapter, Dunkirk was the signal for an intensification of the Canadian effort as it was a warning to Great Britain that she must turn to Canada for more than merely educational orders in the armament field. Unfortunately, in the brief compass of this review, I cannot do more than refer to the excellent chapters of Professor Plumptre and Mr. Borden.

We turn then to Mr. Gibson's essay on finance. Approximately 40 per cent of the national income (1941-42) is required by the government. The expectation is that roughly one-half of the outlay by the treasury will be provided by taxation. This compares with an estimated outlay by the *federal* government in the United States of a little more than one-half of the national income in the fiscal year 1942-43, and the provision of two-fifths of the total expenditures or somewhat more than one-fifth of the national income by federal taxation. Total taxation (all governments) will, however, yield about 30 per cent of the national income.

Mr. Gibson presents a rather ingenious criticism of the point that in periods of unemployment the country should rely on sales of securities paid for out of additional money. Any failure to impose heavy taxes at this point encourages purchases of consumption goods with money earned in the out-

put of war goods. The effects are bound to be inflationary or (when diversions of resources to consumption goods industries follow) to result in a reduction of war output.

On two points, Mr. Gibson's presentation requires correction or amplification. First, he does not make it clear that the payment of taxes out of accumulated balances does not contribute toward a reduction of inflationary pressure; and, second, that the continued rise of production is not an infallible guide of the absence of inflation. Is a rise of output of 5 per cent and a rise of prices of 50 per cent noninflationary?

The next issues are raised by Mr. Taylor's essay on wartime control of prices. The Wartime Prices and Trade Board has ample power to deal with prices: licensing of middlemen, control of distribution, establishment of monopoly buying practices, fixing of prices, etc. In general, the Board has tended to keep prices down through improvements in the distributive process, control of margins, fixation of prices and deals with British buying monopolies. In the case of cod liver oil, however, the Board confronted with the loss of its most important source of supply, encouraged a large mark-up in prices in order to stimulate the saving of fish livers.

Mr. Taylor recognizes the functions of price changes in the economic system. He, therefore, objects to price freezing; but, on the other hand, he realises that, when demand arises rapidly and supply is inelastic in the short run, a rise of prices will not contribute greatly to the provisioning of markets. In the reviewer's opinion, Mr. Taylor overemphasises the contribution to price stability that may be made by adequate monetary and fiscal measures. At least, he fails to note that general measures (*e.g.*, a rise of taxation) directed toward specific scarcities, are wasteful, in that the required dose must be large relatively to the effect to be obtained. It is much better to cut prices and demand in each particular market where scarcities prevail. Then particular controls can be supplemented by general measures.

It is too bad that Mr. Taylor does not discuss the Canadian export price policy. Why are exports exempt from ceilings? Why are American purchasers of Canadian newsprint, for example, forced to pay what the traffic will bear? If the answer is the shortage of dollars, then it would still be better to keep prices down and provide Canada with Lease-Lend aid. It is particularly unfortunate that Canada encourages a high export price policy when the United States applies domestic ceilings to the export field. Finally, it is unfortunate for American policy makers that this book was written too late to enlighten us on the price freeze. I, for one, would like to know whether, because all prices are thus kept down and purchasing power continues to rise, the raids on markets are intensified; or whether the announcement of price stability drives potential buyers off the market. If both factors are relevant, which is the more important one?

Two chapters on labor problems, one by the deputy minister and the other by an important trade union official, reveal a difference of viewpoint on the all-important issue of the wage ceiling. Mr. Stewart seems to approve the limitation of wages to the 1926-29 level. Labor was treated well, for the cost of living had fallen 12 per cent since that period. It is provided, more-

over, that although wages do not automatically respond to a rise in the cost of living, adjustments will be made whenever the cost of necessaries of life rise. In this manner, labor is compensated for unavoidable increases in expenditures and yet the rise of wages is kept down to a minimum. Mr. Moore frankly says that the tie-up of wages with the cost of living (the quasi-freeze) was introduced despite the opposition of organized labor.

Perhaps the most brilliant and most helpful chapter in the whole volume is Mr. Rasminsky's contribution on foreign exchange control. Here we have an excellent statement of the Canadian balance of payments, pre-war and war; of the peculiar difficulties of the Exchange Control Board; and of the measures taken to protect the Canadian dollar. Canada's dollar pool became one of its most pressing war problems because it lost many of its former markets; because the United Kingdom, which could pay in free currency or gold only in part, increased its share of Canadian exports; because Canada, which launched on an all-out program long before the United States, had to increase its imports of raw materials at a disproportionate rate; and, finally, large economies in exports to non-sterling countries were required. The Canadians imposed severe restrictions on imports from non-Empire countries; introduced special measures to stimulate imports from sterling countries (thus saving dollars); stopped exports of capital in a much more vigorous fashion than the United Kingdom had; and finally, through the Hyde Park agreement, solved its dollar problem. Under this agreement, the Canadians agreed to provide large amounts of war materials to the United States; and the latter agreed to finance raw materials purchased by the United States for conversion into war orders of the British.

Professor MacGregor's chapter on "The Standard of Living" gives the reader some idea of the extent to which the Canadians have increased output and consumption and to what extent they have relied on capital consumption. A careful study of consumers' budgets suggests where they may be cut. As in the American case, it seems clear that the Canadians will have to take strong measures to curtail consumption and capital formation—as further expansion of output meets increasing obstacles.

This is a very helpful little volume, both because the problems faced are similar to our own and because we can profit from Canadian experience. They have faced many of the issues that now confront us.

SEYMOUR E. HARRIS

Harvard University

The Structural Basis of Indian Economy. By H. VENKATASUBBIAH. (London: Allen and Unwin, Ltd. 1940. Pp. 156. 7*s*. 6*d*.)

Critics of British rule in India, and particularly of Britain's economic policy in India, differ according to the angle chosen, the particular problem under consideration, and the intensity of the consequent result. They fall into three groups. One holds that the policy of the British in India has been definitely and naturally pro-British and anti-Indian. The second contends that they have

done much, but finds fault for their not having done more. The third school of critics who have lost faith in the existing economic order accuse the British for not only being anti-Indian but also as aligning their forces with the reactionary Indian elements—as the princes, the landlords, and the capitalists—and exploiting the poor millions. While Mr. Venkatasubbiah defies classification, he leans toward the second school of thought.

The present study is perhaps the first of its kind in discussing certain selected aspects of Indian economic development, bringing out the inherent conflict between the British imperial interests and those of the Indian people. The introductory chapter discusses the nature of Indian economic development in the light of and as shaped by India's peculiar cultural, institutional, and political forces. The second chapter analyses the occupational distribution of the people. Here the author has gone on the wrong track of assuming, without even attempting to define overpopulation, that India is overpopulated, and argues that in agricultural countries like India the problem of population should be studied more in the Malthusian sense than in the Marxian sense. While pointing out that the population problem in India is pressure on land, he ignores the importance of the twin remedies—the need for rapid industrialization and the extension of cultivation. The author maintains on insufficient data that population pressure exists because environmental conditions are limited in relation to the needs of these remedies.

The third chapter presents an original and interesting discussion of the basic agricultural economy of India. In tracing the historical evolution of the land revenue policy of the government of India, he brings out all the contradictions of the varied systems of land tenure that the vagaries of the British administrators have forced upon the country. In concluding this section the author points out that all these different types of land tenure were "historically created by imperialism for its dual need—progressive cultivation and regular flow of revenue." In practice the former objective has failed, but the latter has been realized to an abnormal degree.

The fourth and final chapter discusses the absence of progressive industrialization and traces the slow and tardy growth of a few Indian industries. Here is an excellent discussion of the problem of British capital in India. According to the author, "The British conquest of India was not of course the result of monopoly capitalism seeking markets, though the basis of earliest armed conflicts with native powers, particularly in Bengal, was economic exploitation. But when the mother country developed an industrial capitalism, its task was only made easier, since it possessed an already conquered territory, thus avoiding the necessity of fighting to gain a market."

In Appendix A there is a "Note on India's Industrial Potentialities in Relation to Her Mineral Resources." It opens with a highly surprising statement: "India is not so rich in minerals as she is usually boasted to be. A general impression has been created by which India's 'enormous mineral wealth' is assumed and 'the lack of enterprise to exploit them' is pitied." Any student familiar with the wealth of India's resources—potential and exploited—will disagree with this sweeping statement. Were this not a brief review, one could paint a factual picture of India's enormous resources on the

one hand and the failure and neglect to industrialize the country on the other. The reviewer is compelled to wonder whether the author is familiar with the publications of the Geological Survey Department of the Government of India. This statement of the wealth or poverty of India's industrial resources can at best be relative and can never be so absolute as the author states. It depends upon whether one is comparing India's resources with those of Japan or China, Canada or Cuba, Great Britain or Guatemala, the United States or Uruguay.

On the whole, Mr. Venkatasubbiah's book is original and well written. The author, who is a graduate in economics of an Indian university, is an associate of the New Fabian Research Bureau in Mysore. This study is a welcome addition to the meagre literature on this subject and should find a place in libraries of American colleges and universities.

S. CHANDRASEKHAR

New York

This Age of Fable, The Political and Economic World We Live In. By GUSTAV STOLPER. (New York: Reynal and Hitchcock. 1942. Pp. xx, 369. $3.00.)

In an impressive volume, which proposes to "be brutally intolerant of lies and insincerity" and whose "ambition [it] is to be popular but also to live up to exacting scientific standards" (p. xix), Dr. Gustav Stolper, formerly editor of *Der deutsche Volkswirt,* sets out to destroy the fables engulfing the minds of an unenlightened public, which in his opinion are responsible for the ordeals and disasters which have befallen our society. Fables, it may be said at the outset, are such theories, views, or arguments which do not happen to find the approval of Dr. Stolper. As there are very few pieces of equipment in our ideological arsenal which are acceptable to him, the number of fables which he is anxious to refute is almost legion. An amazing variety of subjects are treated in rather pompously written, but highly entertaining chapters, so entertaining, indeed, that for the uncritical reader they may disguise a host of fallacies, misrepresentations, and superficial half-truths potentially more dangerous than all the fables which Dr. Stolper desires to destroy.

Reducing his far-flung discussion to its simple and comprehensible kernel, we discover that the entire campaign against the fables boils down to the not wholly unfamiliar assertion that government should keep out of economic affairs. This fundamental contention is corroborated at some length by theoretical arguments and by a few "case-studies" of which the ones on the Soviet Union and Germany are the most outstanding. The digression into the "theoretical field [is] for the benefit of those readers who wish to enrich their knowledge on matters on which everyone talks so glibly and to immunize them against the writers whose fascination thrives on their brilliant ignorance" (p. 146).

Let us see how Dr. Stolper enriches and immunizes his reader. "Economic crises"—we learn—"are to modern society what sicknesses are to the human body. They are not the normal condition of our society, but they are a natural event in the same sense as sickness is natural in the life of a man"

(p. 146). Whereas most people would agree that prophylaxis and therapy have eradicated many sicknesses, Dr. Stolper thinks differently of the sickness with which he is concerned: "Alternation of better and poorer times cannot be helped and should not be helped" (p. 159). Omitting the question why it *should* not be helped, we may inquire why such alternation *cannot* be helped. The author does not leave us without answer. "As long as total investments (direct or indirect) are equal to our total savings the flow of income may go on undisturbed. The decline of business sets in as soon as investments shrink and a part of savings becomes unemployed" (p. 157).

What is the conclusion to be drawn from this statement which, while not "living up to exacting scientific standards," is at least approximately correct? That government should undertake expenditures to such an extent as to offset the deficiency created by the lack of net investment and provide thus for full employment of resources? Not according to Stolper. "Public investment," he says in his usual apodictic fashion, "cannot bring about a boom or, for that matter, full employment . . ." (p. 160). Because "the reduction in the income flow through oversaving cannot be remedied simply by creation of new money, as is popularly believed. Only if the new money induces new investments will its effects be salutary" (p. 159). The present economic situation, however, permits even the man in the street to study the influence of governmental spending on the level of output and employment, but Dr. Stolper has expected this argument and has his answer promptly at hand: ". . . the fact that the Government was so easily able to create boom conditions and full employment by a vast expansion of armament must not mislead to the fallacy that a peace boom is easy to achieve. The crucial difference is that an armament boom is something extraneous, imposed on a peace economy without competing with private business. . . . The amounts spent on defense might suffice to rebuild the American cities. But were this technically feasible and not in its early phases handicapped by shortages of certain categories of labor, it would create such a wholesale destruction of real-estate values that the effect would possibly be a depression exceeding in severity even that of the early 1930's" (p. 162). What does all this amount to? It amounts, at best, to the observation that if deficit spending, increase in public debt, etc., continue to play the rôle of bogey-men in the minds of some economists and business men, they are likely to be permanently counteracted by investment-strikes. The task of the government in that event will certainly become greater and the solution of the problem more difficult. The only lesson to be learned, however, is not that economists should increase the confusion by adding muddled "theories" about "crushing burdens of gigantic debt service" to the existing fallacies but should try hard to study the real implications of a fiscal policy directed at achievement and maintenance of full employment,[1] and help liquidate the fables which are peddled under the name of economic science.

While Dr. Stolper's resentment toward the New Deal and all progressive

[1] The reviewer is well aware of the difficulties and limitations inherent in such a fiscal policy and treats them in a forthcoming article.

economic thought is couched in forms of "scientific" arguments, his disgust for centralized planning in Russia breaks through in the form of unrestrained distortions. A few examples of the way in which he disposes of all the intricate problems presented by economic experience in Russia may suffice. "The result of twenty-five years of socialist Utopia is in supreme degree just what the socialists accuse the capitalist system of being: chaos and disorder, poverty, a total production at about the level achieved by 1914 before the First World War started, and this at the price of a lowering of the living standard (because of the enormous military expenditures), at the price of the enslavement of a great nation, of the degradation and humiliation of human dignity the like of which the world has not known since the days of Jenghiz Khan" (p. 65).

Does he really believe that a country sighing under the impact of chaos, disorder and poverty is able to wage a total war for nearly a year against the most powerful military machine the world has ever seen? And does our author, "brutally intolerant of lies and insincerities," expect that the reader is going to take what he says seriously if he maintains that Russia has today a "total production at about the level achieved by 1914"? That is said in spite of the existence of 500,000 tractors working on Russian soil and entirely produced at home, an airplane construction which makes it possible to withstand a German air offensive on a front of 2,000 miles, an output of steel which amounted to 18 million tons in the year 1940 as compared with 4.2 million tons in the year 1913, and coal mining which yielded 165 million tons in the year 1940 as against 29.1 million tons in the year 1913.

But Dr. Stolper is unimpressed. There was no necessity to increase production, no necessity to build up a powerful armament industry. "After 1921, once Czarist Russia's former allies had definitely given up their attempts to change the revolutionary Russian system by armed intervention the Soviets might have settled down peacefully inside their own sphere" (p. 281). Instead of behaving in such a prudent fashion, ". . . the Red Army has been served and pampered throughout" (p. 307). In addition the planners indulged in "transplanting of existing basic industries from the western parts of Russia to the center [the Urals, Western Siberia] and to the Far East" (p. 282).[2] In order to carry through such devilish—and superfluous!—projects the Bolsheviks disturbed the peasant, who before the First World War "quietly and contentedly . . . tilled the soil and fed himself and the cities . . ." (p. 280), and imposed unnecessary privations upon the population. "Soviet Russia chose without necessity to impose on her people that plight of initial accumulation over again, for now cheap capital from abroad was to be had" (p. 290). Certainly! Loans to Russia were, as everybody

[2] No existing industries were ever "transplanted." In addition to the development of the existing industrial districts, natural wealth of other regions was tapped, partly for strategic reasons, partly because iron ore can only be mined where it is available. On page 268, Dr. Stolper remarks indignantly: ". . . we look at the Siberian vastnesses whose hidden riches were exploited or neglected according to the selfish whims first of the Czarist, then of the Bolshevist Great Russian imperialists." Then it was not "transplantation" after all? And according to whose "whims" should these riches have been exploited? And since when is development of the natural resources of one's own country called "imperialism"?

knows, an especially attractive feature on the capital markets of the financial centers of the world, particularly at 24 to 36 per cent per annum.

Yet Dr. Stolper is not entirely against armament. "Under any system, it would seem, Russia could have afforded a first-rate army. But under a decent system it could, goodness knows, have afforded popular affluence as well" (p. 307). That is indeed an assertion which, if true, would heavily indict the policy of the Russian five-year plans. Unfortunately, there is nothing either in Dr. Stolper's book or in the historical experience of other countries to support this contention. France and England living under "decent systems," to use Dr. Stolper's terminology, had certainly more affluence than Russia. The fate of France is well known and England owes her survival to the existence of the Channel more than to any other single factor. Where would Russia, enjoying no such natural protection, be today had the Russian government followed Dr. Stolper's suggestions? It would seem that Dr. Stolper would not mind if the Germans were to replace the Communist regime. Since according to his theory of imperialism there is no such thing as colonial exploitation, the Russians ought, instead of fighting, to be grateful for the privilege of experiencing the benefits of the German "organizational genius."

Since Dr. Stolper's competence in matters economic and Russian appears, to say the least, rather dubious, let us turn to his discussion of Germany. There is a field where he is regarded as an authority. "Central Europe, in fact, has been socialized or nationalized ever since 1914" (p. 25). ". . . National Socialism in Germany and Fascism in Italy never were anything but socialist orders . . ." (p. 133). Everybody is perfectly free to define socialism and nationalization in any way he pleases. But the definition which is used has to be clearly stated, consistently applied, and, furthermore, make some sense. If governmental interference by itself makes a socialist society, then the term loses all analytical significance. Governmental control in the age of mercantilism was no less rigid than in the Germany of Weimar. It could hardly be said that there is no difference between the "socialism" of this German republic and the "socialism" as established by Hitler. According even to Dr. Stolper, there must have been some. Because, after we are informed that Central Europe has been socialized ever since 1914, we are told that "by that time [Spring, 1938] German economy was completely socialized in everything except the emptied title to property" (p. 327). That these "empty" titles to property still accounted in the year 1938 for 28 per cent of the national income[3] disturbs Dr. Stolper very little. Since Russia and Germany are equally socialist,[4] and since "not one single major war in the last one hundred and fifty years—the capitalist age—had its origins in economic causes or was waged for economic interests" (p. 192), one might ask, why they are fighting the present war. This quite important question for an author preoccupied with the "political and economic world we live in" remains unanswered. We are

[3] Maxine Y. Sweezey, *The Structure of the Nazi Economy* (Cambridge, Harvard Univ. Press, 1941), p. 208.

[4] "Ironically enough . . . this total war (as far as Russia is concerned) does not have to be fought against 'world capitalism' but on the contrary *with* world capitalism against a rival 'socialist economy' " (p. 307).

left just as unenlightened with respect to all other problems connected with German development since 1933. Analysis is replaced by findings such as this: "Hitler's uncanny instinct is his medium-like reaction to the oscillations of the German soul" (p. 317); "From Munich onward German diplomacy was almost grotesquely idiotic" (*ibid.*).

Such samples of factual information and analytical acumen could be easily multiplied. The reviewer regrets to be unable to point to, at least, a few bright spots in the darkness of *This Age of Fable.* He searched for "extenuating circumstances." He found none.

Business Cycles and Fluctuations

Investment and Business Cycles. By JAMES W. ANGELL. (New York: McGraw-Hill. 1941. Pp. xviii, 363. $3.50.)

Prospective readers of a book presumably are most interested in what they stand to gain from it. On this basis I believe we should go first to a group of three chapters (9-11) which, though not explicitly labeled thus, constitute Part II, devoted to the concept of the multiplier. Angell was one of the first to perceive Keynes's error in relating the multiplier to the propensity to consume,[1] since this treats planned saving as if it were all hoarded, and to insist that spending, whether upon consumer's or producer's goods, governs the relation between investment and income increments. The retention of Keynes's definition would indeed permit a *conceptual* distinction between the multiplying force running from a particular increment of public-works investment and *its own* effect upon income on the one hand, and multiplying forces running from any private investment on the other hand, such as might be functionally related to the increased consumption (acceleration principle) or to the increased public investment, or not functionally related to either (routine investment of savings). But if the Keynesian definition is retained, statistical operation is either stopped or utilized in a misleading fashion, since statistics of income will inevitably include the effects of these "other" forces. Angell's definition of a multiplier in terms of the propensity to *spend* not only supplies the actual arithmetic link between money and income—the income or circular velocity of money—but it also permits legitimate statistical operation with the available aggregative figures of money, velocity, and income.

Angell is thus able to utilize his extensive velocity analysis, developed over a number of years, to produce one of the really notable treatments of the multiplier to date. Arithmetically the average circular velocity of money is obtained from the separate velocities of active and hoarded money. Since on the one hand the velocity of active money can be assumed to be practically a

[1] Aside, of course, from the tautological and meaningless definition of this propensity in terms of the multiplier itself; *cf.* Angell, pp. 189-90.

constant through its being rooted in the payment *mores*, and since on the other hand the velocity of hoards is zero, any change in the average circular velocity is normally caused by a change in the relative proportions of active and hoarded money. Thus Angell is able to relate changes in circular velocity to the marginal propensity to spend (or hoard); and by reference to data beginning in 1899, to assign definite values to the latter through working out the average and marginal velocity figures. The results show a noteworthy long-run stability of average velocity and of the relation between money stock and income. Prior to 1929 the marginal and average velocities tended to close conformity at about 3 per annum; thereafter the average fell heavily to 1933, but again assumed relative stability at about 2.19; and the marginal velocities, indicative of increased hoarding, in comparison to the averages respectively for 1929-33 and 1933-39 stood at 4.99 compared to 2.61, and 1.75 compared to 2.19. Aside from short period changes such as those of 1929-33, Angell's equations permit the approximate forecasting of multiplier values. Finally, attention should be directed to his valuable distinction between the "vertical" and the "cumulative" multipliers, referring to its value per unit of time and through infinite time, respectively, and to the contrasting values of the latter under conditions of increasing, constant, and decreasing anticipations (pp. 196-97).

The noteworthy accomplishments of this analysis in relating the multiplier to the propensity to consume and in the statistical elaboration of this concept are in no way impugned by three critical observations which follow. In the first place, the conventional implication seems to have been a multiplier in *real* terms, but Angell has omitted the method of deflating his purely monetary figures. Secondly, while Angell correctly objects to the Keynesian multiplier on the grounds of its assumed constancy of the marginal propensity to consume, it is curious that he holds it to be "rigorously correct" if the latter condition is realized (p. 193), when he has justifiably altogether repudiated the correlation of the multiplier to the propensity to consume. Finally, there is the objection recently offered by Salant that the *lag* of the income effects of new investment cannot be mechanically derived from a period of monetary circulation— unless, I might add, people have no hoards, cannot borrow, or do not "anticipate" income. Otherwise an increment of investment at any point in the economy *may* give rise through favorable anticipations to an immediate increase of expenditures elsewhere, and thus to an immediate increase of income all the way around.

It is impossible to dwell upon the essays in the concluding three chapters, which in effect constitute a Part III on economic policies; just as it is impossible for the reviewer to do more than recommend their sound judgment and careful elaboration. The data presented in the last essay upon defense financing are now obsolete, but the general argument as to the possibilities of marked price advances have been justified by the developments of the past year. The essay on "Government Spending and Business Cycles" (chap. 12) shows the theoretical possibility of a miscarriage of the policy (pp. 211-21); reviews the history of public spending since 1931, which revealed a failure to

prime the pump (pp. 221-34); and finally weighs the dangers of increasing public indebtedness and the eligibility of other cycle controls, such as taxing hoards, central bank devices, and stabilizing the supply of money. In the chapter on "Secular Stagnation and Government Policy," Angell does not agree with the thesis that secular stagnation arises from "an alleged lack of investment opportunities in the purely technical sense," a position which has also been ably represented by Professor Fellner and maintained by others.[2] Angell objects that the closing of the frontier and the declining rate of population increase in the United States considerably antedated the onset of protracted depression; he calls attention to the potentialities of investment in new housing, and refuses to assume a prophetic rôle as to a dearth of technical advances in the future. On the other hand, the obstacles to international trade and finance and the developments under the New Deal adverse to private venture capital seem to him to be adequate to account for the hesitancy of investment. The only regrettable omission is the adverse effect of restrictive measures upon output, including government limitations and private monopolies. Professor Angell's analysis of the causes of lagging investment merits the close attention of all students of the problem.

Angell's theory of business cycles, presented in the first seven chapters of the book, resembles Keynes's more than Mitchell's in its readiness to reduce the whole story to the movement of a very few aggregative variables, a characteristic which is set in relief by the use of a series of highly simplified quasi-historical graphs somewhat after the example set by Kalecki. The great variety of forces such as are involved in Mitchell's description of the self-generating cycle, or in Haberler's painstaking analysis of the stresses and disproportionalities developing in revival or contraction and their complex interplay at the crucial turning points, gives place to the behavior of four magnitudes viewed mathematically as "functions" of anticipations—investment, consumption, income, and money balances. But saving, the chief devil in the Keynesian piece, plays no rôle nor do variations in the rate of interest. Initially (chap. 1) both investment and saving are defined in an *ex ante* sense as schedules of demand for and supply of investment funds; thereafter a curve representing the equilibrating points of a series of such schedules is first labeled "D, S" with a note (p. 25) to the effect that it carries no implication as to the equality or inequality of saving and investment, but later the function is called simply "investment." Somewhere in the process *ex ante* saving and any possible contrasting behavior with *ex ante* investment get lost for the theory, though in a completely covert form they play a very significant rôle in the behavior of hoards. Whether by accident or design the Keynesian propensity to consume also disappears;[3] indeed the diagrams (pp. 34, 37) show consumption

[2] William Fellner, "The Technological Argument of the Stagnation Thesis" *Quart. Jour. of Econ.*, August, 1941, pp. 638-52; Sumner Slichter, "The Conditions of Expansion," *Am. Econ. Rev.*, Vol. XXXII (March, 1942), pp. 1-21; Howard S. Ellis, "Monetary Policy and Investment," *Am. Econ. Rev., Suppl.*, Vol. XXX (March, 1940), pp. 27-43.

[3] Except when the author inadvertently uses this term when he actually means to employ his own concept of "propensity to spend," *e.g.*, pp. 97, 100, 258, 283.

increasing more slowly than income as functions of rising anticipations up to a certain point, but thereafter more *rapidly,* the direct opposite of the Keynesian supposition.

Chapters 5 and 6, setting forth the reasons for abandoning interest rate variations as causally significant for cyclical variations, will puzzle many a reader. Angell distinguishes three concepts: (1) *expected* yields on new investment, (2) *expected* yields on existing assets, and (3) the interest rate, defined as "the current" (or "the market") rates of yield which can be obtained by the purchase of equities (or "physical assets") at current prices. Keynes, he believes (p. 41), represents the amount of new investment as the result of an "equilibrium" (*sic*) between the first type of yield ("the marginal efficiency of capital") and the third type ("the interest rate"); but, says Angell, interest rates (3) are never except accidentally equal to (2) and *a fortiori* are not equal to (1). "The potential purchaser's actions are determined by a comparison of *expected* yields on new investment and on existing assets, but not by a comparison of either of these with current *market* yields on existing assets."[4]

Actually Angell's (1), (2), and (3) are all the same, the marginal efficiency or productivity of capital, and nowhere does he have a rate of interest as a contrasting concept. For surely it is the expected yield on *new* investment (1) which sets the expected yield on *existing* assets (2), aside from the survival of incorrect and by-gone evaluations on the latter which Angell nowhere posits; and as surely it is the *expected* yield on assets (1) or (2) which sets the current *actual* (or market) yield on existing assets (3), unless current valuations have no reference to the future, which cannot be Angell's contention. The "interest rate," as a contrasting concept, is not the yield on *assets,* present or future, but the return on a *money* loan (4). Yields on assets represent the productivity or marginal efficiency of real capital (the "real," "equilibrium," or "natural" rate) in contrast to interest on fluid funds (the "money" rate, or in Keynesian terms, "the" interest rate). This is the necessary contrast which has prevailed from the time of Ricardo through Wicksell to Keynes. Moreover, no one of these writers, including Keynes, maintained a necessary equality of (1) and (4), which Angell incorrectly described as (3): it was a *divergence* which accounted for investment. And it is *this* divergence which is roughly indicated by the contrasting behavior of long-term bond yields and short-term loan rates, which is Angell's only recourse to empirical data in this discussion (p. 45, n. 1).

After this unfortunate excursus into concepts, Angell touches—altogether too briefly (pp. 50-52)—upon the *real* reason for limiting the rôle of interest rates in determining investment, *i.e.,* the importance of other costs, and of variations in expected demand. Finally Angell objects to the Keynesian theory of interest itself on the grounds that market rates and money stock do not move inversely, liquidity preference being constant. The present writer does not view the Keynesian theory as a complete explanation of interest, though

[4] P. 49. The italics are Angell's.

liquidity preference is of course one element. But Angell seems to confuse changes in the liquidity function itself with movements along the schedule (pp. 62-63), which is what Keynes means by a constancy of liquidity preference; at any rate Angell accepts the Keynesian inverse relation of money and interest in an ensuing paragraph (p. 63, bottom).

The abstract theory of business cycles culminates in a "Description of the Cycle" (chap. 8), half of which pertains to the upper turning point (pp. 92-113), two pages to the lower turning point (pp. 113-15), and the rest to general observations on self-generation, exogenous factors, etc.. And it is precisely upon this much-emphasized upper turning point that the theoretical structure is weakest. According to one version (pp. 93-95), the downturn comes about "inexorably" (pp. 99-100) through three forces: (1) an adverse development of costs relatively to prices; (2) a short-run "saturation point" in particular fields; (3) the decrease of the marginal propensity to *consume* and increased hoarding. We learn later (p. 110) that this development is *not* inevitable; that for a time, so far as concerns force (2), investors may turn to other fields; by consequence, aside from rising costs (1), the over-all limitation comes in force (3). But so far as concerns hoarding, more particularly, he elsewhere argues convincingly that "after the expansion is well under way, people hoard little or none of any current *increases* in income but spend all of them either on consumption, or increasingly, on investment," and even a temporary set-back will not prevent the maintenance of current consumption and programs of investment (p. 200, his italics). Indeed the most plausible hypothesis seems to be that the downturn comes in expectations, plans, and the placing of advance orders; the reduction of current spending (*i.e.*, hoarding) comes, as Angell proved statistically in *The Behavior of Money* (pp. 125, 126, 158, 159), "with or after, not before" the peak of most measures of economic activity.

Retrospectively over these chapters, the net yield for the development of cycle theory seems rather meager. Angell's insistence upon the rôle of velocity in increasing the amplitude of cyclical variations offsets the curious intransigeance of Keynesians upon this point; and he is right furthermore in his scepticism of the dominating position sometimes assigned to interest rate variations. The contrasting behavior of *ex ante* saving and investment may have been overemphasized by certain schools, but it may be doubted whether it should be completely abandoned. For the rest, the theory consists essentially in a rigorously simplified version of the acceleration principle and the introduction of "anticipations" as a uni-dimensional independent variable. One is left wondering whether the simplified schemata do not sacrifice too much of the descriptive and analytical value of the recent extended literature on these subjects.

It is to be hoped that the reviewer's lack of enthusiasm for one half of Angell's volume will not interfere with an appreciation of the really distinguished services performed in the second portion.

Public Finance; Fiscal Policy; Taxation

American Public Finance. By WILLIAM J. SHULTZ. 3rd ed. (New York: Prentice-Hall. 1942. Pp. xxiii, 874. Trade edition, $6.00; school, $4.50.)

In spite of the large number of pages in this book, when its format and the space devoted to tax forms in the Appendix are taken into account, it represents one of the briefer treatments of public finance now available. The field, however, is covered in a clear and concise manner. Especially to be commended is the emphasis placed upon the constitutional and legal background necessarily to be taken into account in the development of revenue systems. Ample evidence is presented that "judges are methodically ignorant of what everybody else knows to be true." The attention which is called to the problems arising from intergovernmental relationships is timely, since such problems will undoubtedly assume greater importance in the years immediately ahead.

In some treatments the reader undoubtedly will desire a fuller discussion of the economic consequences involved in addition to the treatment of administrative problems which the author gives so adequately. For example, especially in these days of war financing, a more adequate treatment of the economic consequences of taxation in comparison with borrowing as a method of financing an emergency would be helpful. The question may be raised as to why a chapter should be called Highway Taxes when other chapters are called Property Taxes, Income Taxes, etc. Certainly highways have not been used as a base for taxes, but taxes levied upon other bases have been spent for highways. Other questions, such as using cost as the distinguishing characteristic between a tax and a fee, might be raised, but they would deal with details rather than with the main purpose of the book. In this treatment of American public finance, Professor Shultz has performed a commendable service.

Money and Banking; Short-Term Credit

Exchange Control and the Argentine Market. By VIRGIL SALERA. Stud. in hist., econ. and pub. law no. 485. (New York: Columbia Univ. Press. 1941. Pp. 283. $3.50.)

The history of exchange control in South America offers a rich field for the economist, but up to the present, literature in English has dealt almost exclusively with European experience. Dr. Salera's pioneer study traces the development of Argentine exchange control from its beginning in October 1931 to the middle of 1940. Argentina abandoned the gold standard in December 1929 and for nearly two years had a free exchange market. The immediate occasion for the establishment of exchange control was not a flight of short-term capital of the panic type so common in Europe in that period, but the

withholding of their foreign bills by the great cereal export houses, with a consequent reduction of the supply of exchange.

In its original form Argentine exchange control involved no discrimination as between countries, but inside of two years it became a means of flagrant discrimination against American trade. British exporters had been steadily losing out in Argentina, largely to American exporters, but the United Kingdom continued to be the best customer of Argentina, and in the late 1920's and early 1930's British imports from Argentina had been over twice its exports to that country. With the adoption of protection in Great Britain in 1931, and the trend toward Empire bilateralism represented by the Ottawa agreements, Great Britain, by threats and pressure that savor far more of rough-handed German methods than of the English tradition of commercial policy, forced Argentina to discriminate against American trade in favor of British trade. This was done by granting exchange for imports from Great Britain at a lower rate than for imports from the United States, by surcharges on American imports, by purchases by government agencies in Great Britain at substantially higher prices than those quoted in the United States, and by import quotas.

Salera thoroughly documents his thesis that the British were largely responsible for pushing Argentina to its extreme forms of bilateralism. Those who think of German bilateral trade policy as the principal obstacle to the acceptance of the Hull trade policy in South America will find this account a revealing and perhaps a disillusioning one. Salera's conclusion is that Argentina is not likely to return to a nondiscriminatory commercial policy by British initiative (p. 245), but that the United States, by its tariff policy, and a relaxation of the present arbitrary quarantine regulations, could reduce Argentina's dependence on the British market, and play a positive rôle in bringing an abandonment of narrow bilateralism in South America.

Salera makes the well-taken point that Argentine exchange control cannot be appraised in terms applicable to European experience, and states that "there has not been the slightest attempt to pervert exchange control to the furtherance of totalitarian ends" (p. 253 n.). The study also indicates little attempt to use exchange control as a substitute for tariffs in building up local industries.

The story that Salera tells is well worth telling, and the book represents careful research and competent analysis. It is unfortunate that the manuscript was not subjected to a rigorous editorial revision before publication. As it stands, the ponderous style oversteps even the standards charitably applied to doctoral theses. References to British and American exports to Argentina as "originations" (p. 239); "the proliferation of discriminatory preferences" (p. 147); an "unwithstandable" temptation (p. 177); peso appreciation "inexorably on the march" (p. 185); the authorities that had "given birth" to a classification (p. 221); and "the maintenance of a dual market type of exchange control in the free market of which the whole gamut of transactions might be consummated" (p. 201), are a few samples of what the reader faces if he is to battle his way through the book.

FRANK WHITSON FETTER

Haverford College

Ceylon Currency and Banking. By B. R. SHENOY (Madras: Longmans Green. 1941. Pp. xl, 300.)

This book dealing with the history, institutions and problems of Ceylon's currency and banking is designed for students of monetary problems not only of the island of Ceylon but also in a general way of India. While there is a fairly large amount of literature discussing the problems of Indian money and banking, there has been no complete and scientific study of Ceylon's monetary problems. Ceylon, though not under the government of India, has rested in the shadow of her great neighbor. Recently, however, since she was placed upon the agenda of Japan's aggressive expansion, keen interest has been evinced in the peoples and problems of the island which has a population as large as that of the continent of Australia. While this book does not discuss the political institutions and economic problems of the island, the treatment is broad enough to indicate the general economic problems of Ceylon. In this respect it fills a long felt gap.

The first two chapters, nearly forty pages, trace the island's currency history, embracing the successive rule of native, Portugese, and Dutch administrations. The author in his Preface expresses his hesitation in retaining this material in the book. While it is true that the subject matter concerning the genesis and growth of the currency system is the special concern of the numismatist and the currency historian, it has interest for even the general reader and serves as a desirable introduction for the currency system that exists now under the British rule in Ceylon.

The next two chapters deal with the monetary problems that the early British rulers were confronted with and how they attacked them. There is a discussion here of the events that led to the appointment of the Swettenham Currency Commission of 1869 and the Lascelles Currency Commission of 1902, their respective recommendations and the government's action thereon. The fifth chapter enquires into the island's paper currency.

The three succeeding chapters present an able and interesting exposition of the banking systems and problems in Ceylon. The exchange banks, the joint stock banks and the indigenous banking—all receive due attention. All the exchange banks in the island are entirely British, unlike India where there are several non-British exchange banks. Apart from the branches of the Imperial Bank of India and the special position of the Reserve Bank of India, in Ceylon, there is only one Indian joint stock bank in Ceylon. The author has dealt briefly with Chettiar banking in Ceylon. The Chettiars of South India form a commercial caste and are a banking community. They have done pioneering work in this direction in most Asiatic countries. According to some critics they are very welcome since they provide cheap short- as well as long-term credit. Others consider them unscrupulous exploiters. There has never been a scientific and impartial study of their banking methods in the light of modern conditions. I wish the author had given more space to this question, since the foreign student is more interested in this institution than in the joint stock and exchange banks with whose operations he is more familiar. It would also have been well for the author to explain Indian terms, such as *Hundis,* for the benefit of the American student.

The last two chapters deal with the (Draft) Paper Currency Ordinance of 1939 and the present position of the Ceylon rupee and its relation with the Indian rupee and British sterling. The book closes with an excellent discussion on the case for and against the creation of a central bank for Ceylon. The present exchange control regulations of the island, introduced to meet the war situation, form the subject of an Appendix. Sir Cecil H. Kisch recommends the book in his Foreword.

The author, a graduate of both an Indian University and the London School of Economics, is now a lecturer in economics at the Ceylon University College, Colombo, and as such is well qualified to write this book. This study, the first of its kind for the island, is scientific, clear, and informative and as such is a welcome addition to the meagre literature on the monetary problems of countries in the East.

S. CHANDRASEKHAR

New York

Business Finance; Insurance; Investments; Securities Markets

The Investor and the Securities Act. By HOMER V. CHERRINGTON. (Washington: American Council on Public Affairs, 1942. Pp. x, 253. Cloth, $3.25; paper, $2.50.)

Dr. Cherrington, professor of commerce at the University of Iowa, has limited his examination to the Securities act of 1933, the so-called "Truth in Securities Law." Although he recognizes the disadvantage of the private investigator who does not have access to the files of the Securities and Exchange Commission, the author thinks it worth while to use the available information for an appraisal of the law and its administration to date.

The book opens with a discussion of the evils which were responsible for the legislation. The closing chapter reviews the results of the legislation in relation to each of these practices. Other chapters deal with the proposals for reform prior to 1933, and an outline of the provisions of the law and the work of the Commission. A brief examination of the British experience is sandwiched in between these chapters. The remainder of the book surveys the most significant forms of misrepresentation with which the Commission has been confronted; the position of underwriters and the problems of underwriting; and the responsibility of accountants under the Commission's rules and decisions. The material is well selected, and the presentation is clear; the treatment, in spots, is sketchy. The book also suffers from the effort to assess the relation of government and the investor without considering the pertinent legislation in its entirety.

The comparison of the Securities act and the English experience is serviceable. It shows how much further we have gone in our attempt to protect the investor. Perhaps our tardiness explains the difference. There is an interesting recital of some of the earlier and generally forgotten suggestions for reform in the financial world. Omission of the late Justice Brandeis's work

in this direction seems strange. The treatment of such topics as "beating the gun" in the sale of securities and private placement is realistic. The author seems to take no definite position with reference to the waiting period. He perceives the irony implicit in barring the small buyer—both institutional and individual—from investing in the many high-grade issues sold privately to large institutions in increasing volume. Dr. Cherrington, however, produces no evidence that this tendency has arisen solely out of the provisions of the Securities act. The litigation in connection with the liability of underwriters does not seem to justify the impression that the provisions of the law are unduly harsh.

The letter of deficiency requesting amendments in registration statements is a potent instrument of administrative policy. The Commission has discretion to decide whether or not amendments may postpone the effective date of the registration statement. Yet, as the author points out, in the absence of a formal dissent, it is not ordinarily possible without examination of amendments to individual statements to determine how the Commission has handled the particular deficiency problems (p. 139). He remarks: "A democratic society is in a potentially dangerous situation when the policies of an administrative agency which has far reaching power to regulate capital markets can be known only by those who are on the inside." No alternative is proposed. The suggestion is made that the Commission should go further in providing investigators with information, since they are confused by the prolixity of the usual prospectus. Dr. Cherrington thinks that investors inescapably tend to regard the registration of securities as evidence of the Commission's approval.

I must take issue with the conclusion that the flotation of new securites by small corporations has been severely handicapped by the costs growing out of the requirements of the Securities act. This is a hardy myth. The exemptions of small issues are duly described by the author (p. 108). The costs of flotations of relatively small issues shown in detail in the published studies of the Commission prove conclusively that by far the greatest item of expense is the underwriting fee, or selling commission. The costs of registration, including legal, accounting and engineering expenses, are small.

The book contains an index and a bibliography. Unfortunately, the recent hearings on amendments to the Securities act before the House Committee on Interstate and Foreign Commerce on H.R. 4344, etc., have added substantially to the data which could have been used. Nevertheless, this study will serve those who wish to consult a brief, general survey.

RUDOLPH L. WEISSMAN

New York

The Voting Trust: A Device for Corporate Control. By JOHN ANTON LEAVITT. (New York: Columbia Univ. Press. 1941. Pp. 216. $2.50.)

The amount of economic literature devoted to the voting trust has always been relatively limited. The appearance of Mr. Leavitt's book is therefore

welcome, although it does not pretend to be a treatise on the subject nor within its modest scope is the treatment free of certain shortcomings.

The primary concern of this study has been to examine the voting trust in relation to the locus and administration of control within the corporation. The voting trust is depicted as a device whose prime characteristic is the "fixing" of control in the hands of a specific group—a result which is achieved by an exchange of stock for trust certificates between stockholder and trustees, whereby the former relinquishes to the latter his right to vote. Sometimes this amounts only to perpetuating the control already exercised by a management group; on other occasions the control may actually pass from one group to another before it becomes crystallized. Aside from two brief chapters on history and legal status, the author has devoted his attention largely to exploring the nature of this device, the methods by which it transfers and fixes control, and some of the implications of its adoption.

In one chapter, for example, are described in unusual detail the provisions which have customarily comprised the voting trust agreement. Included are over twenty subjects, covering everything from the preamble down to the various methods by which a trust may be terminated. Another chapter is devoted to a consideration of the uses for the voting trust. A group found to occur most frequently are those associated with corporate reorganization, at which time prior creditors or bankers often insist upon the creation of a trust in order that they may be assured of the quality and stability of the management until the enterprise is thoroughly rehabilitated. Its applicability to new corporations and to public control of old ones (*e.g.*, to expedite the dissolution of a combination) is also considered. The positions of the trustee and of the security holder are accorded consideration in two additional chapters. On the one hand, the trustee is found seldom to be a heavy stockholder, frequently to represent banking groups, and to have interests not necessarily identical with those of the corporation. The stockholder, on the other hand, having forfeited his franchise, is no longer able to protect his interests against possible encroachment nor even to inform himself as to whether they are in jeopardy.

The voting trust is thereby demonstrated to be one more device for separating ownership and control of corporations and concentrating that control in relatively few hands. It not only offers no guarantee of sound management; it openly invites abuse. Accordingly, if its use is to continue, the author recommends a more careful regulatory policy, especially in the direction of securing a shorter life for the average trust, providing more publicity concerning trust activities, and reducing the immunity of the trustees.

Restricted though the scope of this study is admitted to be, it leaves much to be desired both in form and content. The general structure could have been considerably improved by the inclusion of a concise introduction, by the relegation of countless illustrative cases to footnotes or summary tables, and by more careful organization throughout. Among the more noticeable substantive shortcomings are a failure to give sufficient attention to the real estate trust and a tendency to provide categorical answers to many of the

issues raised when a further resort to facts seemed warranted. Nevertheless, this volume contributes some very worth-while exploratory and taxonomical spadework.

JAMES B. ECKERT

Washington, D.C.

The Securities Market and How It Works. By BIRL E. SHULTZ. (New York and London: Harper. 1942. Pp. ix, 433. $5.00.)

The Stock Market. By CHARLES AMOS DICE and WILFORD JOHN EITEMAN. 2nd ed. (New York and London: McGraw-Hill. 1941. Pp. xvi, 486. $4.00.)

The Securities Market and How It Works is an outgrowth of the course until recently given by the New York Stock Exchange Institute for employees of the Exchange. A more advanced text than its predecessor, *Stock Exchange Procedure*, the present volume is designed to cover the more "fundamental and technical" aspects of the securities market. It is especially addressed to those engaged in some phase of the securities business and their customers as well as providing a text for college classes. The editor and senior author was formerly director of the New York Stock Exchange Institute, the predecessor of the present New York Institute of Finance. As collaborators he had certain members of the institute staff and individuals connected with prominent brokerage houses.

Although there is no such formal division, the treatment falls logically into three parts. The first deals with the history and functions of the stock exchange, especially the New York Stock Exchange, history and procedure of listing securities, and types of securities and their flotation. The second division has to do with the procedure of trading in stocks and bonds on the floor of the Exchange, covering such items as the execution of orders, specialists, odd-lot trading, short-selling, etc. The third division treats of the procedure in the brokerage office in connection with customers' orders and accounts. It explains the mechanics of opening and handling of accounts, commissions and taxes, preparation and analysis of the customer's statement, margin regulations and practices, clearance and delivery of securities, etc., while also giving an introduction to financial statement analysis. A concluding chapter deals briefly with some current problems of the Exchange.

Every step in the complicated procedure of the security markets is explained in pointed detail and clarified by innumerable illustrations. One gains the conviction as he reads that here, for the first time, is available a thorough and authentic treatment of the technical business and procedure of the securities markets written from the inside. It deserves to succeed all previous books of a similar nature.

At the end of each chapter is found a list of questions and tests especially designed for candidates for employment or promotion within the sphere of the brokerage and exchange business. To many readers this volume will come as a revelation of things long desired but until now unobtainable.

The Stock Exchange is a second edition of the senior author's earlier work of the same name and follows in its chapter headings the plan of the first edition. One more chapter on "The Price of Stocks" is added.

The reader will welcome a more than doubling of charts and figures, while noting the omission of numerous tables found in the first edition and also a contraction of the Appendix on "Stock Market Terminology." Illustrative material has been brought down to date, which adds freshness to the treatment.

The volume, like the first edition, is written from the customer's point of view and deals not so much with technical procedure in the mechanism of the market as with the relationship of the customer to the market. Interest is maintained in security price movements as exemplified on the exchange. The analysis of causes, however, remains restricted as in the first edition.

In the final chapter (which is new) the traditional theory of the relationship of price to earnings is treated but too briefly and inadequately, as are also the principles of growth stocks and leverage. More valuable is the new material dealing with manipulation and the federal acts of 1933 and 1934 relating to securities and exchanges which has been included.

Public Control of Business; Public Administration; National Defense and War

The New Economic Warfare. By Antonin Basch. (New York: Columbia Univ. Press. 1941. Pp. xvi, 190. $1.75.)

This series of lectures delivered at Columbia University in the summer of 1941, is a broad and not very analytical discussion of war economics, totalitarian organization of economic affairs, and world politics. One chapter (the fourth) is devoted to the topic announced on the cover: economic warfare. The most valuable parts of the book are the descriptions of economic policies of nazi Germany and Great Britain. While the specific problems of the war economy are well seen, the fundamental economic changes of our time, which form the framework of the present experiments in war economics, do not find clear recognition, and little is done to give a meaning to the observed failures and successes.

In the first chapter, dealing with economic preparation for war, Dr. Basch limits the discussion to the preparations of nazi Germany and the explanation of their success. The economic causes of war receive a very superficial treatment. The author points to a list of maladjustments in international trade relationships before the present war; but he does not seem to see any logical connection between the spirit of the Versailles Treaty and the economic and political conflicts that developed. Given a longer lease on time,

Basch argues, the ideas of Versailles might have led to a workable world system; unfortunately, their execution was "handicapped by all the repercussions of the war" (p. 4).

This argument seems futile. If a political world system meets the problems of the time, it will scarcely need more than twenty years before it begins to manifest its power. The conditions created by the treaty favored the development of rivalries and new conflicts, and there is only too much agreement between its spirit and the futile attempts of the victorious powers to smother the explosive forces in the world while providing new fuel for them. Firmly anchored in the Treaty of Versailles were the policies to rebuild a powerful German capitalism while withholding from its masters a share in the ruling of the world, to erect a barrier of satellite states around Germany without providing for their prosperity, and to liberalize the colonial system without heeding the demands for industrialization and political independence of the colonial peoples. After these policies had developed their full effect and the great depression had disintegrated the leading nations, the nazi plan of world conquest and its early successes were a logical development. Dr. Basch limits himself to observing the outcome of this process. The absence of concerted opposition to nazi expansion, its temporary encouragement by "democratic" diplomacy, remain as unexplained as aggression itself.

Chapter 2 gives a summary of typical problems of the war economy. Dr. Basch stresses the impossibility of carrying on total war without drafts on civilian consumption and the nation's material wealth, and shows the limited usefulness of anti-depression policies in wartime, when the achievement of victory is the supreme goal. He sees no way in which the principles of private business can cope with the war situation: "All productive equipment, all industry, is to be treated as if it were one big enterprise governed from one place and by one set of principles" (p. 69), a condition which he sees already reached by Germany and Great Britain in the present war. Careful students of war economics will agree with these observations.

One minor point may be raised in connection with this chapter. Although the state assumes the rôle of a monopolistic supplier in certain fields, one wonders how "monopolistic price theory may be applied in determining optimum prices . . . under which the national economy would best meet the war requirements" (p. 49). Does Dr. Basch propose that the British government sell wheat to the people at prices that net a maximum profit to the treasury? Perhaps, the author has been thinking of monop*sony* rather than monopoly; rational monopsonistic policies may be very useful if applied by the procurement agencies of the military forces.

Chapter 3 gives an account of important features of the British and German war economies, and chapter 4 discusses economic warfare. Some important facts are clearly seen. Dr. Basch states that Germany's "economic position as a whole, even for a long war, was . . . stronger than in 1914" (p. 129). (This seems to refer to the end of 1940.) Systematic preparation and organization of available resources, military strategy determined by the principle of speedy successes over one enemy after the other, efficient exploitation of

conquered territories brought about this result. Although it is far from being a consumers' paradise, nazi Europe cannot be conquered by economic strangulation, useful as this method remains as a companion of military blows.

The author arrives at the conclusion that structurally the German and British war economies show a great deal of similarity. Both countries adopted anti-inflationary fiscal and price policies. The remaining differences between the two systems can be explained—to some extent—by the delay in the starting of the British war economy.

There are a few minor points in the discussion of the German war economy that may attract criticism. The rôle of price control in the German war economy seems somewhat exaggerated when described as "the most important item in the general policy and especially in war financing" (p. 74). Given the immediate control of industrial production by the state and the existing fiscal policy, price control appears of comparatively small importance. It might better be described as an auxiliary tool.

Although Dr. Basch recognizes the comprehensive economic control power of the nazi government, he expects trouble from the huge savings deposits that are accumulating in Germany. True, if the immense blocked purchasing power were suddenly released, it would upset the markets for consumption goods. But are there any reasons to suppose that it will be let loose during the war? And if the release takes place after the end of the war, is it so difficult to bring about a gradual transition? At present, at any rate, one can hardly agree with Dr. Basch that these savings indicate a serious weakness in Germany's noninflationary financial policy; they are one of its main pillars. It seems that the inflationary dangers inherent in the increase of the Reichsmark circulation are similarly overrated. If we are interested in finding real instead of imaginary weaknesses of Germany, we should turn to an analysis of transportation and other practical problems of the nazi war economy. Dr. Basch's book, unfortunately, does not give much help in this direction.

Chapter 5, "From War to Peace," is devoted to an examination of nazi plans for the post-war world and reflections about democratic peace plans. The problems of transition from war to peace are scarcely touched. The best part of this chapter is the matter of fact account of the nazi schemes and their partial realization in the occupied countries.

The criticism of the nazi scheme is extremely weak. It is said to be "materialistic," not to respect "basic human rights"; but there is little about the problem of its compatibility with the trends in the world economy. The juxtaposition of a "free world based on an international exchange of commodities and following fundamental economic principles . . . a world in which the principle of legality must be made to prevail again" does not add to the force of the criticism of the "New Order." What type of international society? What fundamental economic principles? Whose laws?

Dr. Basch does not choose to answer these questions, except by reference to an old political scheme and a very vague program. The old political scheme is the federation of the Danube countries, an idea once held dear by French

governments, some of the states of the Petite Entente, and cherished up to our days by the house of Hapsburg. This idea never seemed to satisfy all of the nations involved; it was discarded time and again in the twenty years following Versailles since it never found the powerful sponsor that could put it into practice and maintain it against the opposition. Moreover, this idea never provided a solution to the basic European problem, which is the problem of Germany. The same is true for the Oslo block which Dr. Basch seems to recommend for resuscitation. If the "United States of Europe" do not provide a solution, as Basch intimates, only a still larger block of united nations will. Regional sovereignties within Europe belong in the pre-airplane age.

Dr. Basch's economic program is neither new nor realistic. It aims at a marriage of state control and capitalism in which both spouses are expected to reign supreme. In the "negotiated free economy" that he proposes, the state is supposed to prevent unemployment while private enterprise governs the remainder or, as Dr. Basch says, the major part, of economic life. This looks like the old devil in new disguise. State interference designed to prevent unemployment effectively means state control of production and investment planning. Fiscal and monetary policy will do only as long as the government does not feel under an absolute mandate to do away with unemployment. Only if the state is willing to risk the recurrence of depressions, can it leave the planning of production with uncoördinated corporate and governmental agencies. Private capital does not flourish in the atmosphere of "limited" state interference where it is supposed to assume risks without holding the supreme command. The result of this form of arrangement is too fresh in people's memory to make the plan respectable: government hamstringing business, and business hamstringing government. How the two rivals that tend to paralyze each other in protracted struggle can be turned into an efficient team, Dr. Basch fails to show. He refers the problem to the democratic nations.

In some places it seems that Dr. Basch would be quite willing to give the state the first and last word in economic decisions; but in deference to a vague concept of "liberty" he holds back with an unequivocal statement. There are other instances, however, where the author seems satisfied with such weak arguments against government planning as the "absence of a code of values" or the failure of certain governments in economic tasks, governments that were unprepared, unwilling, or unauthorized to do the job.

HORST MENDERSHAUSEN

Bennington College

Arms and the Aftermath. By PERRIN STRYKER (Boston: Houghton Mifflin. 1942. Pp. viii, 157. $1.75.)

The author, a former feature writer for *Fortune* magazine, attempts to cover, in breezy fashion, five topics: (1) industry's war record during 1917-1918, (2) technical information on mass production of war implements, (3) possible post-war results of plant expansions, (4) a report on the "various

1941 attitudes of manufacturers toward war business and their opinions about the future," and (5) suggestions as to "the intentions of the Government in a post-emergency world" (p. 20).

Stryker finds ample evidence in the experiences of World War I to demonstrate that construction, conversion, and operation of plants devoted to production of war goods divert resources from the civilian sector of the economy. In spite of this obvious lesson, he regards the present task of equipping for "defensive" war as a load to be superimposed upon industry's normal production schedules. There is, moreover, a tendency to identify industrial efficiency with the number of operations carried on under one roof. The difficulties involved in subcontracting are, accordingly, emphasized and the need for parceling out tasks belittled.

Regardless of the government's offer to buy specialized equipment required for war production, some business men, Stryker finds, spurn the risks of entering new and perhaps temporary lines of production. They do not want to manufacture war implements according to confusing specifications at a time when their usual wares can be sold through the regular channels of trade at prices bolstered by the rising volume of income paid out by adventurers who have taken war contracts. For these producers of war goods the author foretells a doleful future. To admonish his readers about the problems of post-war industrial adjustment, he summons the specter of stark, bleak and idle factories. Consequently, these "excess" plants will have to be sterilized in order to preserve the processes of "orderly" marketing. Business men, apparently, have not heard and do not act on Hansen's thesis[1] that the nation's entire productive resources and abilities can be employed to rebuild our capital equipment and to achieve a high level of real income for civilians.

The author's formulation of problems connected with the future relations of government and business appears garish to the extreme. He envisages a "post-emergency government" dominated by Isador Lubin and Leon Henderson, signers of the minority report submitted by the T.N.E.C. Another bogey on the horizon is government control in behalf of the consumer. "Federal concern for the consumer promises to be one of the major characteristics of the future New Deal. . . . For once the government takes the consumer under its wing; it will have to abandon its traditional role as the protector of the maker and seller" (p. 151). Stryker manifests little consciousness of responsibilities to rehabilitate a war-sick and poverty-ridden world. The only indication, indeed, comes by way of a suggestion that producers of peacetime goods at war's end are going to get an immense tactical advantage over their rivals in the scramble for markets. This time advantage, coupled with mercantilistic practices, may fix the industrial pattern and secure for decades the gains obtained through initial penetration of markets.

Considerable weight should be attached to this book as an expression of

[1] Alvin H. Hansen, *After the War—Full Employment* (Washington, 1942), No. 2 in the National Resources Planning Board series, *Post-War Planning*. Also A. H. Hansen and C. P. Kindleberger, "The Economic Tasks of the Post-War World," *Foreign Affairs*, vol. xx, Apr., 1942, p. 466.

the recent past thought of those who direct operations of an important sector of American industry. Stryker's report, together with the revelations of the Truman Committee, troubles those who are convinced that nothing less than a desperate production drive can supply in time the tools required for military victory. This is a book, then, to read for a point of view, and, like some other influential books extant today, not to be judged entirely by the consistency of its argument.

WILLIAM BRAY

Cornell University

Industrial Organization; Price and Production Policies; Business Methods

Hollywood: The Movie Colony, the Movie Makers. By LEO C. ROSTEN. (New York: Harcourt-Brace. 1941. Pp. x, 436. $4.00.)

Mr. Rosten, with the help of a large grant from the Carnegie Corporation and the Rockefeller Foundation and a staff of ten assistants, has given us a delightful and penetrating account of the social and professional life of the moving picture capital. During three years of investigation in Hollywood he gained a wide entrée. On the basis of this experience he gives a vivid picture of the work-patterns, customs, and attitudes of the more prominent groups in the industry. This volume describes the life of the movie colony and analyzes in detail the characteristics of the producers, directors, writers, and actors. A future volume is to include an economic analysis of the industry and a discussion of its labor relations. The present volume is a social anthropological study of Hollywood on the "Middletown" pattern, and I shall leave an evaluation of it as such to scientists in that field.

An interesting chapter on "Politics over Hollywood" includes a description of the depths to which the movie producers sank when they tarnished their silver screens with fabricated newsreels against Upton Sinclair during the California gubernatorial campaign in 1934. Had the chapter been written a few months later it would probably have contained an account of the ill-starred congressional investigation of alleged pro-war propaganda in movie plays and of the misuse of the newsreels to present far-fetched arguments against compulsory joint income-tax returns. If these cases had been included, the author might well have been led to conclude that the producers' abuse of their power to influence public opinions has been limited chiefly to issues directly affecting their personal financial interests.

Economic interest in the volume centers chiefly in the chapter on "The Big Money." Rosten gives the size and number of the big incomes. While disclaiming any intention of discussing the reasons for the high salaries, he appears to attribute them to the profitability of the industry and the box-office value of scarce talent. "Movie profits go to the elite—in Hollywood and New York—and not to the stockholders. . . . Management gets big money for itself and big money for the talent it employs" (p. 86). The economic justification for high salaries to able producers is supported by an analysis

of 39 pictures, indicating that "in well over half of the cases, the higher the salary of the producer, the higher the net profits to the studio from the pictures which that producer made" (p. 277). It is questionable whether this analysis is sufficiently conclusive to warrant publication. Another instance of extensive analysis of inadequate material is the dissection of the personal expenditures of sixteen individuals. On the whole, I think the author summarizes the spending habits best when he quotes Ken Murray: "Hollywood is the place where you spend more than you make, on things you don't need, to impress people you don't like" (p. 103).

The chief weakness of the book comes from a labored attempt to make it scientific, which, so far as an economist can judge, results rather in making it pseudo-scientific. Rosten has taken his measuring rod into every cranny of Hollywood, and cluttered some parts of his otherwise fascinating book with insignificant data. Appendix H gives, for example, a statistical analysis by sex, age and location of persons whose fan letters were received during one month by *one* actor and *one* actress. Postcards constituted just 66.8 per cent of this correspondence. What social scientist has been eagerly awaiting this source material? The general discussion of the content of the correspondence is much more illuminating.

Rosten deluged Hollywood with questionnaires. The answers enabled him to analyze statistically the producers, directors, writers, and actors with reference to their age, birthplace, education, experience, earnings, marital history, and professional attitudes. Those in each occupational group who replied to the questionnaire constitute the sample, which is checked for representativeness. But many persons included in the sample did not answer all the questions, and doubts arise that the returns for particular questions constitute representative samples. After reading Rosten's questionnaires one can only marvel that he received as many answers as he did.

The book is very well written, except for a few instances of carelessness. The number of movie theaters, for example, is variously given from different sources as 15,115 and 17,000. In giving data per person and per family, a ratio of 5 to the family is used in one case and 3.77 in another. And in the text it is stated that 47.4 per cent of 251 actors *finished* high school but did not attend college, whereas the data in the Appendix permit one to calculate that 26.89 per cent of the 47.4 per cent did not complete the four years.

This volume, in spite of occasional overdevelopment of quantitative measurement, does give a vivid and clever account of work and play in the movie capital. There are probably few other people that could have seen behind the façade of Hollywood as penetratingly as Rosten has done. It is to be hoped that he will complete his second volume, using the material he has gathered on the economics of the industry, as soon as he can be spared from his present position as Director of the Motion Picture Section of the Office of Facts and Figures. His characterization of the industry as geared to a mass market but unable to use the methods of mass production holds promise of some interesting analysis.

W. H. McPHERSON

Oberlin College

Marketing; Domestic Trade

Marketing. By FLOYD L. VAUGHAN. (New York: Farrar and Rinehart. 1942. Pp. xi, 639. $3.50.)

Yet another textbook in marketing! The need—if indeed there be a need—according to the author, Professor Vaughan of the University of Oklahoma, is for a treatment that emphasizes "principles rather than technique" and that proceeds primarily "from an economic rather than an acquistive point of view." Complaint about high marketing cost and consumer insistence upon more information about the quality of products bespeak the importance of the economic approach. This treatise aims to analyze from an economic point of view the reasons for the relatively high cost of marketing and to offer suggestions as to what may be done to increase market efficiency. The book meets this test to a reasonable degree. The author presents the usual features of marketing in an orthodox but adequate fashion and in the final chapters of the volume he gives sound explanations for higher cost of marketing than of manufacturing and advances recommendations for dealing with the situation in the light of accepted economic principles. Herein lies the chief merit of the book.

Like any freshly printed text in a field that is changing so rapidly as that of marketing, the book has the added merit of presenting the most recent advances in technique. Such developments as the super-market (pp. 225-227) and the agricultural legislation of 1936 and 1938, which seek to restrict the output of farm products in order to raise prices (p. 309), are well treated in the text. Another good feature is the questions and problems appended to each chapter for class discussion.

The book is divided into six parts. Part One gives the approach and discusses the psychology of human wants. The next six chapters (Part Two) describe the orthodox functions of marketing. Of the various approaches to the study of marketing the author pays his respects to the functional approach as "the most important" (p. 10). But subordinate to the functions at any given time, it is important to know "the psychological appeals, physical facilities, mediums, and practices in marketing." Accordingly, Part Three describes the mediums that perform these functions (private enterprises, coöperative associations, and the government); and Part Four treats of the practices which these mediums employ—salesmanship and advertising, credit, price policies, fair competition, merchandise turnover and stock control, and market research. The next five chapters (Part Five) present methods of marketing different classes of products and contrasts the methods of handling production goods (farm products, extracted products, and manufactured goods) and consumption goods (convenience goods and shopping lines). Part Six contains an appraisal of the marketing system primarily from the standpoint of cost, giving reasons for the increase in marketing cost and offering recommendations.

The final chapters of the book are by far the most significant. Herein the author sets forth three general explanations of the increase in the cost of

marketing. One is the fact that marketing is subject to the economic principle of decreasing cost to a much lesser extent than is manufacturing. A second reason is higher transportation costs for longer hauls between producer and consumer, added sales efforts, and other increases in marketing functions. A third explanation consists of monopoly, unfair competition, and additional margin-widening acquisitive practices. The recommendations follow in terms of these factors—flexible freight rates, decrease or improvement in the functions of marketing, less advertising—and these deserve a firm nod of approval.

Carleton College

Transportation; Communication; Public Utilities

Essays in Transportation in Honour of W. T. Jackman. By H. A. INNIS, editor. (Toronto: Univ. of Toronto Press. 1941. Pp. viii, 165. $2.50.)

This small volume, which carries a foreword by the Reverend H. J. Cody, president of the University of Toronto, and an introduction by Professor Alexander Brady, is made up of lectures presented in honor of Professor Jackman upon his recent retirement after completing a quarter-century of service at Toronto. For the most part the contributors are his former students and present or former colleagues. An exception is Professor C. Lloyd Wilson of the Wharton School who, on behalf of fellow workers in transportation south of the border, pays warm tribute to Professor Jackman for his noteworthy contributions both to scholarship and to student training in the field. The essays or lectures differ considerably in extent and in the level of interest and professional insight they envisage. Some, and possibly all, are worth the attention of specialists in the particular fields.

Professor G. P. deT. Glazebrook of the department of history of the University of Toronto deals with "Nationalism and Internationalism on Canadian Waterways" and discusses the contributions and limitations of water transportation as a basis for political unity in Canada and the bearing of the Canadian waterways on the relations of Canada and the United States. "Is it too fanciful," he concludes, "to imagine that what an historian has aptly called 'the commercial empire of the St. Lawrence,' based on economic and national motives, may be transformed into a political empire of the St. Lawrence, child of its generation, jointly cherished by the Republic and the Dominion?" (P. 16.) Professor Herbert E. Dougall of Northwestern University, in "Some Comparisons in Canadian and American Railway Finance," finds that the railroad problems of the two countries, formerly quite different, now reach common ground in the obstacles to financial health that beset both systems. But the countries have differed in their response, in that American losses have fallen mainly on security owners while those in Canada

have largely been assumed by the state. After an extensive factual examination of the "Principal International and Interterritorial Class-rate Structures of North America," Mr. Frank L. Barton, chief of the economics section of the Tennessee Valley Authority, concludes that "the levels of class rates applying to Official Territory from Southern, Southwestern, and Western Trunk-Line Territories, and Eastern Canada are apparently made with no relation to density of traffic or costs of railroad operation within the territories from which the class rates apply" (p. 55). Professor Wilson, in his survey of "Some Basic Problems in the Public Regulation of Transportation," provides a concise summary of the perennial and the more recently emphasized problems and stresses their importance.

The factors making for high cost of movement of farm products in Canada are explored by Professor W. M. Drummond of the Ontario Agricultural College in an essay on "Transportation and Canadian Agriculture," and some suggestions are made for reducing the cost. In the lengthiest of the discussions Mr. Norman D. Wilson, an engineer, in treating "Some Problems of Urban Transportation," sets forth the difficulties of providing city transport facilities in the motor era and surveys the experience of a number of Canadian cities. The bearing upon policy of the presence of municipal ownership and the trend toward "free wheel transit," by busses and trolley-busses, are stressed.

Mr. W. G. Scott's essay, "An Aspect of the British Railways Act, 1921," follows a broader plan than the title may suggest. Discussing the disappointing operation of the standard-revenue provision of the 1921 law, the counterpart of the 1920 "rule of rate making" in this country, he paints such a picture of the use of transport control to throttle the railways' competitors as should horrify those American students who now voice alarm over the straightjacketing tendencies of American regulation. It would appear that consumer-protection has largely disappeared from the British system of control. Mr. Scott believes that the end of protecting railroad investors could better have been achieved through outright subsidy, but he does not declare himself as to the worthiness of the end itself.

The final essay, on "Recent Developments in Balance of International Payments Statistics," by Mr. Herbert Marshall of the Bureau of Statistics of the Dominion Government, departs from the transportation theme but deals with the not unrelated matter of the recent progress made in Canada in determining the volume of foreign trade movements and tourist expenditures. The revised estimate gives Canada a credit from tourists of 78 million dollars in 1939 instead of the 166 millions previously announced.

Four closely packed pages are required to list the publications of Professor Jackman. Best known among them are his two-volume treatise on *The Development of Transportation in Modern England* and his *Economics of Transportation* and *Economic Principles of Transportation,* which reflect his Canadian setting.

University of Michigan

Air Transportation. By CLAUDE E. PUFFER. (Philadelphia: Blakiston. 1941. Pp. xxiv, 675. $3.75.)

Air Mail Payment and the Government. By FRANCIS A. SPENCER. (Washington: Brookings Instit. 1941. Pp. xii, 402. $3.00.)

Air Transportation in the United States: Its Growth as a Business. By HUGH KNOWLTON. (Chicago: Univ. of Chicago Press. 1941. Pp. vii, 72. $1.25.)

The first two of these books are works of substantial scholarship. The third is a sketchy little book by an investment banker who is a member of the board of directors of Eastern Air Lines. It contains some information of interest on factors influencing the growth of air transportation, but one is forced to wonder how it happened to be published "through aid of a special fund for geographic study and research."

The books by Puffer and Spencer respectively were both completed in the summer of 1941, and appeared almost simultaneously. They cover much of the same ground, but with completely different types of approach. Puffer discusses all phases of current federal law and administration relating to scheduled air transportation. Spencer limits his scope, not too rigorously, to the place of air mail payments in the development of air transportation.

Puffer's book seems destined to convey an unfavorable first reaction to many readers. It has a formidable 16-page table of contents and an introductory chapter which is exceedingly dull. As one ploughs through the book, however, the amount of sheer labor which went into it can hardly fail to inspire some respect.

The most valuable part of the book is probably the lengthy chapter which presents the accumulated experience in the issuance of certificates of public convenience and necessity for new air carriers. Partly because of the subsidized character of the industry, the pressure for certificates has been great, and there have been complex special problems. At present, expansion of route mileage has been brought to a halt because of the war, but there is every reason to expect rapid expansion in the post-war period. The precedents so far established in connection with certificates for new services may then become of considerable importance.

Other major chapters deal with rate making for air mail service and for transportation of persons and property. The discussion of air mail rate making has both the advantages and disadvantages of an intensive analysis of the printed decisions. It collates the precedents, but does not penetrate very far behind the mask of officialdom. Other chapters deal with the economic and legal characteristics of the industry, the regulatory agency, and the regulatory activities concerned with accounting, corporate relationships, labor relations, and safety.

The treatment of decreasing costs is careful and elaborate, but there is almost no discussion of technological progress in the industry and its economic implications. This is a strange omission in a book on air transportation. At pages 302, 367, and 386, conclusions about rate-making policy, subsidy payments, and industry profitability in the future are postulated upon the ex-

pectation that costs will continue to decline merely because the industry is one of decreasing costs in the static sense.

As a critical study, the book is lacking in impact. Significant appraisals of current practice are included, but tend to become lost in a wilderness of detail. For most readers the book would have been greatly improved by a rigorous condensation. Certainly no undergraduate should be compelled to read it in its entirety as a textbook.

On the other hand, the mature student who has a specialized interest in almost any phase of the economics of air transportation will find the book very useful. Everything relating to current regulatory practice seems to be there, conscientiously compiled, well arranged, and carefully indexed.

Spencer's book, as previously noted, is concerned primarily with the issues connected with air mail payments. Since most of the public controversy so far in the air transportation field has been related to the mail payments, they provide a convenient organizing theme. The main structure of the book is chronological.

After an introductory chapter, Spencer covers the development up to 1934, reworking the ground covered by the present writer in *The Economics of Air Mail Transportation,* but with a fresh look at the source material. He then deals somewhat noncommittally with the cancellation of the air mail contracts and reports subsequent developments during the period of Army operation.

About half of the book, seven chapters, is devoted to the Air Mail act of 1934 and its administration by the Interstate Commerce Commission. "A review of those chapters," as Spencer says (p. 225), "indicates that the Air Mail act of 1934 contained statutory defects and that its administration by the ICC was not altogether satisfactory." This is an understatement. In particular, parts of chapter XII deserve a place in any collection of examples of administrative ineptitude in the field of public regulation.

The three chapters on the Civil Aeronautics Authority and Board afford an interesting sequel. The record indicates that, while before 1938 an old experienced agency was doing a new job badly with its left hand, after 1938 a new agency which was willing to give the most concentrated attention found itself trapped at first by its own inexperience.

Throughout the whole period since the cancellation episode in 1934, the type of regulatory action needed by the industry has been constantly changing. The administrative activities actually attempted, moreover, have been largely on a trial and error basis. In the background, not too well concealed, there have been the numerous feuds and animosities carried over from the cancellation fight.

Spencer's book has the great merit that it deals realistically with the problems which have actually been uppermost in the minds of the officials of the regulatory agency, air transport executives, and members of Congress. His is not a book written in a library about a distant governmental activity. Despite a considerable amount of tactful phrasing, he manages to convey

in pointed fashion the results of much penetrating observation.

The economic analysis is competent and sufficiently extended for the purposes in hand, but the book is as much a study in public administration as in economics. Because of its success in dealing with an area where economic and administrative issues can never be entirely disentangled, it is a significant contribution to a better understanding of how government functions in the field of economic regulation.

Economic Geography; Regional Planning; Urban Land; Housing

Economic Geography of the United States. By BERNHARD OSTROLENK. (Chicago: Richard D. Irwin. 1941. Pp. xvi, 804. $4.00.)

Professor Ostrolenk begins his book with an apology: "Economic geography, like history, needs to be constantly reinterpreted, reëvaluated and rewritten in the light of new technological developments." Indeed, there are many elementary textbooks in economic geography. One should think that there are innumerable tasks more worthy of the talent and effort of a professor of economics than adding another to the stock. Mr. Ostrolenk redeems himself by introducing new types of evidence and new viewpoints into the field of economic geography texts.

His plan is excellent. He starts from the proposition that the appraisal of resources, the significance of their geographic distribution, and their contribution to human welfare are constantly in flux, are currently affected by changes in technology, demand patterns, institutions and public policy. Hence, economic geography should be discussed in terms of just these changes, instead of merely describing how much of what is where.

Dealing with coal resources, for instance, he discusses the painful agonies of a competitive and poorly organized industry faced with a declining demand for its product and the emergence of a powerful labor union, and tells of the rescue attempts by the government. In connection with the iron and steel industry, he explains—too sketchily but with laudable intentions—the workings and effects of the basing point price system and price leadership. Agriculture is shown reeling from the blows of trade barriers and losses at export markets, and a brief survey of the major public policies designed to cushion the shock and to help farmers to adjust their production to the new demand situation is presented.

On the whole, the selection of factual materials in tables, charts and maps is made judiciously according to their relevance to these dynamic aspects. Hardly a figure or map is shown which does not have a significant place in the analysis or argument developed in the text. The unceasing attempt of the author to give meaning to facts and to select them from an amorphous pile, according to their relevance to major issues of economic and social

welfare, renders his book outstanding among its none too exciting companions.

The deliberate and systematic focus upon social welfare and living standards places the geographic location of resources in a position coördinate with the various technological, economic and institutional factors determining the conditions under which the resources are utilized by people. Abundance of natural resources in itself does not make people rich. The author stresses, by means of many concrete examples, the growth of public policies designed to facilitate people's efforts to adjust resource uses to changing production techniques and demand patterns in such a way that general welfare and living standards be increased. Similarly, he points to other public policies which are hampering such adjustments. The arguments regarding these problems are presented cogently and without dogmatism.

So much for the merits of the book. Its main deficiency lies in the lack of conciseness with which this constructive approach is carried through into the details of the various sections. Frequent references are made to the fact that whenever "pecuniary costs" and "true costs" fail to coincide, economic and social maladjustments are bound to arise. Yet no satisfactory definitions of these two concepts of cost are given. In the chapter on Conservation, for example, we find this statement: "To say that it does not pay to conserve soil, or to reforest waste land, or promote health, or educate and train young people is merely an evidence of improper application of the pecuniary system. Conservation of resources frequently demands that pecuniary accounting be ignored, that values be measured in other than pecuniary terms" (p. 775). In the first place, it is poor logic to throw soil conservation or reforestation in the same category with health and education; and, secondly, we are entitled to know what value measures beside pecuniary ones the author is contemplating.

Another example: in the chapter on transportation, 20 pages are devoted to a simple listing of various railroad lines, without any reference to traffic loads or other economic-geographic factors; while the economic-geographic railroad problem par excellence, the making of freight rate schedules and their effect upon regional specialization, receives 7½ lines merely stating that there is such a problem.

Finally, I deplore the author's aversion to introducing analytical concepts and simplified models of functional relationships between crucial factors as aids for understanding the processes governing the location of industries and regional specialization. An elementary knowledge of the principles of proportionality of factors, of comparative advantage, of maximizing social product values, etc., is indispensable to students in their endeavor to gain insight into the dynamic aspects of economic geography.

The book is divided into five parts: Geography, Power, Metals and Minerals, Agricultural Resources, and Movement and Conservation. A very informative chapter on "New Resources and New Industries" is contributed by Professor John F. Bell, and two chapters on "Tobacco and Sugar" by Professor J. J. Gottsegen. The discussion of each of the major resources begins with a brief comparison of America's productive capacity with that

of other countries, giving perspective to America's position relative to the world as a whole. Recent technological changes, changes in demand, and relevant public policies are traced for each major industry in their effects upon geographic location, intensity of resource utilization, and living conditions of the people employed in that industry. The structure of ownership and control and the industrial policies and practices regarding output, marketing and pricing are sketched for the various industries, with varying degrees of lucidity. The review questions at the end of each chapter are skillfully designed to stimulate thinking on the part of the student.

Among the texts in economic geography dealing primarily with the United States which have come to my attention Professor Ostrolenk's book is by far the most thought-provoking and deserves a prominent place in its field.

RAINER SCHICKELE

Iowa State College

Southern Industry and Regional Development. By HARRIET L. HERRING. (Chapel Hill: Univ. of North Carolina Press. 1940. Pp. xiv, 103. $1.00.)

To secure that needed balance between agriculture and manufacturing in southern states, certain general principles and factual data are needed. To use the words of the author of this timely and enlightening book on the industrial growth of the South: "This story proposes one such unifying principle which may be useful to planners: an application to the manufacturing industry of Professor Howard W. Odum's principle of optimum production. It supplies some simple—it is hoped not oversimplified—indices that may be useful to agencies trying to encourage manufacturing."

This book emphasizes first the fact that the South is a definite part of the nation and the welfare of the nation is affected by the welfare of this part; second, that the South, to be at its best, needs the development of all its people and capacities.

The material is divided into six chapters, dealing first with an optimum manufacturing economy for the Southeast. It then logically goes into a discussion of manufacturing for the nation, manufacturing for the region, manufacturing for regional balance, optimum production and opportunity, and finally, a statistical picture of the entire situation. A well-planned Index simplifies the finding of particular data. Numerous charts and graphs, found throughout the book, add to the effectiveness of the information presented.

In bringing to the front the problems that confront and impede the development of manufacturing in the South, and for presenting clearly the opportunities for future development, Miss Herring's book is a valuable document.

Labor and Industrial Relations

The Kansas Industrial Court, an Experiment in Compulsory Arbitration. By DOMENICO GAGLIARDO. Univ. of Kansas pub., soc. sci. stud. (Lawrence: Univ. of Kansas Press. 1941. Pp. viii, 264.)

As the reader of Professor Gagliardo's excellent little book on the Kansas Industrial Court proceeds through its pages he is likely to be increasingly impressed by certain similarities between the history of the court and the Paul Bunyan yarn concerning logging operations on the Pyramid Forty. This tract was so high "it took a man a week to see the top, or seven men could do it in a day if they all looked together." Among the animals that lived there was the Pinnacle Grouse. It "had only one wing—and that was a big one. . . . With one wing big that way she could fly round and round in little circles or big circles, which ever she liked, but of course, anyone might know, she never could go straight ahead—not the way she was built."[1]

After noting that "strikes again present a serious problem and once more restrictive legislation is being called for," the author states that his study is designed "to point out the successes and failures of compulsory arbitration in Kansas, . . . to serve as a warning to those who place their hopes in panaceas; and to explore the limits within which compulsion in the settlement of labor disputes may properly be applied in a democracy" (p. v). In carrying out these purposes he made extensive use of legislative debates, court decisions, contemporary newspaper accounts, official correspondence, and unpublished manuscripts; moreover, he secured the personal help of individuals who had taken an active part in the controversies that raged around the court. As a result his readers will be able to "see the top" in much less than a week. The first chapter sketches the political and economic background, both national and local, of the law creating the court. Here as elsewhere Professor Gagliardo pulls no punches. He quotes President Wilson's castigation of mob violence as "that 'disgraceful evil' which added 'to German lies about the United States, what her most gifted liars' could not 'improve upon by way of calumny' " (p. 3); and states that the "national hysteria was reflected in Kansas" (p. 13). With reference to a passage in ch. 74 of the Laws of 1920 of Kansas he declares that, "The severity of this indictment and its palpable falsity are eloquent evidence that, in judging our foreign born and native born of foreign parentage, reason had completely abdicated and rank prejudice reigned supreme" (p. 15).

The fact that the court was built so that it would "fly round and round in little circles or big circles" is revealed in the circumstances, among others, that "No special qualifications were required for those serving as judges" (pp. 42, 201); and that its presiding judge could claim that "We had no precedent to guide us." As the author points out there were precedents from the Australian Commonwealth Arbitration Court, "and the fact that they were not used or even referred to indicates how narrow was the basis of knowledge and experience upon which the court was built and conducted" (p. 235). The

[1] *Cf.* Esther Shephard, *Paul Bunyan*, pp. 23-32.

evidence that the Kansas body did fly around in circles is scattered through this book; one of the best of Professor Gagliardo's comments on its procedure appears on pages 78-79.

In at least one respect, however, it must be admitted that the author's testimony indicates that the Kansas grouse flew straight. Concerning the packing house workers' walk-out of 1921-22, he writes that the court "merely exerted all of its influence to break the strike, offering as an excuse a new interpretation of its jurisdiction. Its effectiveness was in the field of strike-breaking and not in that of adjudication" (pp. 159-60).

In the final chapter he both generalizes and qualifies this criticism: "It is fair to say that the Industrial Court Law was regarded by its makers as a strike-breaking device of the first order, although it must be added that they also believed it made strikes unnecessary and therefore unjustifiable" (p. 233). Connected with these observations is the author's conclusion that, though unions were specifically recognized in the law and collective bargaining authorized, "the fundamental purpose of the act was to reduce unions to a state of impotency . . ." (p. 239). Numerous passages show, however, that he recognizes the relation between this attitude and the type of union leadership represented by Alexander Howat of the coal miners.

Like much legislation of recent years, the Kansas Industrial Court act provided that if any section or provision of it should be declared unconstitutional, the remainder was not to be affected. As is generally known, the U. S. Supreme Court in early 1923 held it contrary to the Constitution for the state to regulate wages in the meat-packing industry, "at least under any but the most extraordinary circumstances," and subsequently "denied the state's right to regulate hours and overtime rates by a system of compulsory arbitration" (p. 245). These decisions, the changes in the relation of the court to the Public Utilities Commission, the abolition of the court, and other events described in detail by Professor Gagliardo finally reduced the original statute to a condition approximating that of another of Paul Bunyan's animals, the Ring-tailed Bavalorous, which after tangling with the Blue Ox, had little left but the ringed tail. In spite of this it remains true that "much more" of the law "has been left intact than is generally supposed" (p. 247).

The author's treatment of his third objective—an exploration of the "limits within which compulsion in the settlement of labor disputes may properly be applied in a democracy"—deserves more space than can be found in a review of reasonable length. Because of the affinity of some of his distinctions and arguments to those presented by the Webbs nearly fifty years ago in *Industrial Democracy*, it is surprising to find no mention of that classic work.

CHARLES A. GULICK, JR.

University of California

Ideologies and American Labor. By PAUL K. CROSSER. (New York: Oxford Univ. Press. 1941. Pp. xvi, 221. $2.50.)

There are two ways of developing labor theory. The one starts with an all-embracing glance at Western history, discovers that it is like a body of water

in a lock canal, proceeds to formulate the qualitative uniqueness of each section of the "canal," especially its "ideology," and then appraises the concrete labor action of our own time by the closeness with which it is guided by the ideology appropriate for the time. This is the way of the author of this book.

The other way is to study labor action from the standpoint of the labor organizations endeavoring to establish themselves in their social environment and, at the same time, to mold that environment by building new institutions, such as industrial government, in accord with labor's "home-grown" ideology. Such an unselfconscious ideology is quite different from an ideology in the grand manner as viewed from a lofty height, but it has the merit of springing from the soil and of being understood by Tom, Dick, and Harry.

The author is a Marxist, but in his thinking and manner of exposition his basic Marxism has passed through the bluing process of the latter-day German sociology. Hence, on the one hand, the airtight compartmentalizing of Western history into the town artisan period, the capitalist period, and the proletarian period; and, on the other hand, his formulation of three corresponding "ideologies": the "harmony in the estate," the "balance in marketing," and the "struggle among classes." These ideologies formulated with a truly astounding erudition in Part I are correlated in Part II with three types of American labor relations: paternalistic unionism, liberalistic unionism, and revolutionary unionism. Under the first, he groups the movements prior to the American Federation of Labor as well as the welfare-ism of Henry Ford; under the second, nearly all the subsequent unionism; under the third, the class struggle unionism from DeLeon to Foster. He has to admit serious ideological hangovers, for how else can one account for the ideological oneness of the CIO and the AFL, both of which remain stuck in the liberalistic bargaining phase? But he is supremely confident that, in the future, American labor's ideology will distinctly show that it belongs to the part of the canal past the capitalistic lock.

The reviewer has nothing but admiration for the author's wide reading and dialectical skill. However, he prefers the other interpretation of American unionism which sees it develop first the "pure and simple" type when the sovereignty of American government was confronted with the stronger sovereignty of American business and now, under our very eyes, reinterpreting its basic "job conscious" ideology by raising its sights to take in the political hinterland of the job. This it does because, in our own day, government has moved into the centre of the arena not only as the regulator, but also as the creator of job opportunities. In this fashion, American labor is moving along both materially and ideologically, but with the enormous advantage that it is avoiding the danger of a flank left hanging in the air, resulting from an ideological breach with the bulk of the middle classes still devoted to the liberalistic "balance in marketing," albeit with such amendments as the A.A.A. and the like.

SELIG PERLMAN

University of Wisconsin

Stars and Strikes: Unionization of Hollywood. By MURRAY ROSS. (New York: Columbia Univ. Press. 1941. Pp. x, 233. $2.75.)

The movie industry is no less glamorous than its stars. Since it is widely publicized and since its product is highly personalized, popular interest centers in it more than in any other industry. The special characteristics of the industry are reflected in its collective bargaining techniques. The variety of its employees results in an unusual diversity of labor relations problems. For all these reasons it is fortunate that this history of the organization of the employees engaged in producing motion pictures has been added to the growing list of special industry studies in the labor field.

Here is a centralized, large-scale industry making an unstandardized product. The production of each movie is largely a separate enterprise, with many employees necessarily hired on an individual contract basis. Employment for a majority of the workers is peculiarly irregular. Salary rates defy standardization, and bear little relationship to annual earnings. Employee demands have included such unusual points as a minimum duration for layoffs and the allocation of screen credits to writers. The industry has become thoroughly organized although no major strike has ever been won by the instigating union.

Dr. Ross's main title, of course, gives little indication of the scope of his book. The volume deals not only with stars but also with other screen actors, extras, writers, and craftsmen and, in passing, with directors, musicians, technicians, and office workers. It has much less to say about strikes than about the ebb and flow and interrelationships of numerous labor organizations; for there have been very few strikes in the movies as compared with other recently organized industries.

One of the peculiarities of the industry is the unusual degree of uniformity in management labor policy. The first major attempt at unionization in 1916 led the companies to form the Motion Picture Producers' Association, which, with its successors, has been the medium for achieving this unification.

Dr. Ross places merited emphasis on the bargaining machinery established in 1926 by the Studio Basic Agreement, covering the stagehands, carpenters, electricians, painters, and musicians. This agreement places all negotiation in the hands of a joint committee, whose employee representatives are the presidents of the five national and international unions. The author explains why this restriction upon the functions of the local unions and their officials has checked strikes, but a more extensive analysis of its relation to the development of dictatorship in some of the unions would have been appropriate. Special attention is devoted to the "Alliance" as the dominant union in the group. The Alliance, representing the stagehands and several smaller technical groups in the studios and the projection machine operators in the theaters, was greatly weakened in 1933 by the loss of its strike to obtain recognition for the sound men; but when its new president, George E. Browne, in 1935 demonstrated his ability to shut down movie theaters, the producers were induced to grant his closed-shop demands. "By this single stroke, Browne compelled some twelve thousand reluctant workers to join his union at a time when he had no more than a hundred members on all the studio lots" (p. 192).

It was then that the Alliance locals were subjected to the dictatorial control of Browne and his notorious William Bioff.

Special attention is inevitably given to the Academy of Motion Picture Arts and Sciences, whose creation in 1927 retarded the unionization of Hollywood's talent groups. Through 1935 the Academy consistently obtained more concessions for the actors and writers than they were able to gain through other channels. Control of the Academy and its five branches (for producers, directors, writers, actors, and technicians) was vested in a select few. "There was little exaggeration in Equity's claim that the producers controlled the destiny of the Academy. . . . The founding of the Academy was a master stroke of producer ingenuity; its successful operation resulted from actor acquiescence in its policies" (pp. 41, 42). But after 1933 many of its members became increasingly distrustful, and formed their separate guilds.

The detailed account of the lengthy negotiations during the N.R.A. period and the description of the rise of the Screen Actors' Guild and the Screen Writers' Guild to the status of contracting agents complete the main themes of the story. Considerable space is fortunately given to an analysis of the position of the extras (whose average annual earnings in 1940 were $361.03) and an explanation of the steps that have been taken to improve their lot.

There are some indications that Dr. Ross judges the success of labor relations largely on the basis of the absence of strikes. He uses this standard in commending the undemocratic negotiation machinery established by the Studio Basic Agreement (p. 15). He praises the Academy for its considerable peaceful accomplishments. "The Academy was for years an outstanding example of a successful industry-wide employee representation plan," and its formation was "one of the most original contributions to industrial relations in America" (pp. 214-15). And again, he appears to criticize the Wagner act when he says that it "was meant to reduce industrial strife by guaranteeing collective bargaining. Under its aegis the studios have known scarcely a single quiet day" (p. 191).

Dr. Ross has filled his book with interesting material that is not elsewhere readily available. He has made an extensive study of the documents and records on his subject. His use of field work and personal interview appears, however, to have been much more restricted. The attitudes and emotions of the employees are to some extent illuminated by the discussions of their various grievances; but there is no "close-up" of the producers, and we are given but a slight basis for judging their actions, policies, and motives. In fact the book as a whole gives the general impression that the chief struggle involved in the unionization of the industry was between rival unions rather than between the unions and management.

Since the book covers a variety of separately organized employee groups, the question of arrangement of material is extremely difficult; but this problem could have been met more successfully. If a more continuous treatment had been given to the experience of the craftsmen, the extras, and the actors and writers, the reader would have much less of a task in piecing together the many broken threads of the narrative.

I wish that Dr. Ross's volume might have been somewhat more extensive.

Further detail and explanation would be welcome at many points. More thorough evaluation should be possible without marring the objectivity of the treatment. The author himself raises several questions that he realizes are only partially answered. An introductory chapter on the peculiarities of the industry that influence its labor relations would help to orient the reader, though these characteristics gradually come to light as the account progresses.

In view of the movie industry's popular appeal and the great range of its labor problems, this volume is assured a wide reading by those interested in industrial relations. Illustrations drawn from its pages can probably be guaranteed to keep any labor class at attention.

W. H. McPherson

Oberlin College

Wartime Developments in Government-Employer-Worker Collaboration. (Montreal: Internat. Labour Office. 1941. Pp. 163. $1.00.)

This publication is a supplement to *Methods of Collaboration between the Public Authorities, Workers' Organizations and Employers' Organizations* which was prepared and published as a report to the International Labour Conference originally scheduled to be held in June, 1940, at Geneva. Though the book is a supplement, it contains an independent report on the development of collaboration between government, employers' and workers' organizations during the period of the present war. It covers intensively the developments in Great Britain and the United States, and, more briefly, those in Australia, Canada, India, New Zealand and the Union of South Africa. A chapter on Continental Europe describes how the German system of forced labor organizations has been expanded into the conquered and occupied countries, with Sweden and Switzerland as exceptions.

Among the democratic nations England obviously has gone farthest in the voluntary collaboration between trade unions, employer organizations and the government. Tripartite advisory and administrative boards have been formed centrally, by districts, and locally; and their activities have been extended from wage negotiation and arbitration, and prevention of strikes to price, supply, man power and efficiency problems. Collaboration also is extended to questions of draft and deferment, of industrial training and dilution of industrial skills and to seamen's and factory workers' welfare. Some industries have set up special production and employment boards. Finally the trade unions are coöperating in the discussion of post-war reconstruction. Development in the other Empire countries have followed the English example to a large extent.

For the United States of America, it is stressed that the war effort is directed not so much by the existing government departments as by specially created war boards, and that the collaboration has chiefly been carried on by appointing outstanding employer and trade union men to government boards. They join the boards as leading individuals, not as representatives of their respective organizations. The review of developments in the United States,

therefore, is chiefly a description of the forming, reforming, and duties of the different government war boards. The actual collaboration of the employers and the trade unions has been somewhat overlooked.

For the German-held countries, the existence of collaboration is denied, as collaboration is defined as voluntary coöperation, presupposing free and independent organizations of labor and management. This does not dispute the fact that the German government uses the "Labor Front" extensively to whip labor into line.

The advantage of the publication is that it renders a broad international review of developments in the relations between government, labor, and management, and of the new war agencies. Lacking is a critical evaluation of these developments. Collaboration, for instance, means not only increasing influence of the unions in government but also the opposite. There is the further question of efficiency. How do the many boards affect the speed of industrial conversion and efficiency in the new war industries? Is union influence in management really compatible with speed-ups which, after all, might be necessary? Nevertheless, the book reports on deep reaching transformations, especially in the British labor-government-management set-up, for which it deserves our full attention.

Social Insurance; Relief; Pensions; Public Welfare

Swedish Unemployment Policy—1914 to 1940. By HARRISON CLARK. Introduction by SUMNER H. SLICHTER. (Washington: Am. Council on Public Affairs. 1941. Pp. 179. Cloth, $3.25; paper, $2.75.)

This book contains a very good summary of Swedish policies for relieving and reducing unemployment during World War I, during the post-war depression following 1920, and during the period of moderate depression and remarkable recovery from 1930 through 1940. The unemployment programs of both the Conservative and Social Democratic governments in the 1920's and 1930's are explained with abundant statistical material and references. The disadvantages of work relief, the advantages of an expansionist program to combat depressions, and Sweden's wartime labor policy are well explained.

General summaries are, of course, open to specific criticisms. Perhaps the author should have been somewhat more critical of the conclusions of others. This seems to be true in the case of the alleged causes of an increase of "permanent unemployment" in Sweden in the 1920's (pp. 60-62), which neglects both monetary and Keynesian analysis, and it seems to be true also of statements regarding the "international margin" (pp. 132-34, 152) to the effect that an easy-money program in 1932 and 1933 was not possible until the central bank had acquired a sufficient reserve of foreign exchange. In fact, an easy-money program with a decline in the exchange value of the krona

would have helped, and did help to a degree, to build up Sweden's foreign exchange reserve by checking imports, by stimulating exports, and by encouraging home rather than foreign investment. The statement (p. 131) that domestic monetary control following the abandonment of gold in 1931 "failed to stimulate industrial production" also could be challenged.

Although in an introduction Professor Sumner Slichter emphasizes cost-price relationships and wage cuts in building, the Social Democratic government actually followed a Keynesian policy—indeed, the reports of the Unemployment Commission in 1934 and 1935 foreshadowed much of Keynes's *General Theory*—and, as Dr. Clark points out, it was the absence of general wage cuts along with government subsidies, government diversion of income from savers to consumers, government aid in reducing interest rates, and migration to the cities that helped to stimulate investment, housing, and employment (pp. 157-59).

Wartime controls to permit rationing of labor and economic planning in the labor market have been much more complete in Sweden than in this country. As early as 1940 Swedish employers were required by law to hire through public labor exchanges; public funds were appropriated for transporting workers and their families to important work; legislation regarding night work for women, maximum hours, and vacations had in some instances been suspended; and arrangements for labor priorities had been made. Such policies are necessary in order to assure the most effective utilization of existing man power in the national interest.

RICHARD A. LESTER

Washington, D.C.

TITLES OF NEW BOOKS

Economic Theory; General Works

ATTEBERRY, G. C., AUBLE, J. L. and HUNT, E. F. *Introduction to social science, a survey of social problems.* Vol. II. Foreword by LOUIS WIRTH. (New York: Macmillan. 1942. Pp. xix, 800. $4.)

BOHLMAN, H. W. and BOHLMAN, M. E. McC. *Our economic problems.* Heath's correlated soc. stud. (Boston: Heath. 1942. Pp. 608. $2.)
A high school textbook.

BROWN, H. G. *Basic principles of economics and their significance for public policy.* (Columbia, Mo.: Lucas Brothers. 1942. Pp. xvii, 542.)

BUCK, P. W. *The politics of mercantilism.* (New York: Holt. 1942. Pp. viii, 240. $2.)

BULLINGER, C. E. *Engineering economic analysis.* (New York: McGraw-Hill. 1942. Pp. xi, 359. $3.50.)

BYE, R. T. *Questions and exercises on the principles of economics.* Rev. ed. (New York: Crofts. 1941. Pp. 134. $1.)

KNIGHT, B. W. *Economic principles in practice.* Rev. ed. (New York: Farrar and Rinehart. 1942. Pp. xiv, 659.)

KUZNETS, S. S., and others. *National income and its composition, 1919-1938.* 2 vols. Pub. no. 40. (New York: Nat. Bur. of Econ. Research. 1941. Pp. 959. $5.)

MACIVER, R. M. *Social causation.* Soc. sci. ser. (Boston: Ginn. 1942. Pp. x, 414. $3.50.)

MARGET, A. W. *The theory of prices; a re-examination of the central problems of monetary theory.* Vol. 2. Prentice-Hall econ. ser. (New York: Prentice-Hall. 1942. Pp. xxv, 802. $6.)

PEGG, C. H., and others. *American society and the changing world.* (New York: Crofts. Pp. 614. $3.50.)
This college textbook in social science attempts to view American society and its problems as a part of a dynamic interdependent world now in the throes of swift transition.

WINSOR, E. and EVANS, R. W., compilers. *Land, labor, and wealth; a handbook of economic terms.* (Caldwell, Idaho: Caxton Printers. Pp. 117. $2.)
The meaning of some fundamental economic terms explained through quotations from economic works and articles.

Contemporary civilization source book: Part 1, sections 5-12. (New York: Columbia Univ. Press. 1941. Various pages. $3.)

Economic History

BECKER, C. L. *The Declaration of Independence; a study in the history of political ideas.* New ed. (New York: Knopf. 1942. Pp. 303. $3.)
A new introduction by the author appears in this new edition. The book has been out of print for some time.

BIDWELL, P. W. and FALCONER, J. I. *History of agriculture in the northern United States, 1620-1860.* Carnegie Inst. pub., no. 358. (New York: Peter Smith. 1942. Pp. 512. $7.50.)

BOGART, E. L. *Economic history of Europe, 1760-1939.* Longmans econ. ser. (New York: Longmans Green. 1942. Pp. xiii, 734. $4.50.)

CARY, M. and HAARHOFF, T. J. *Life and thought in the Greek and Roman world.* (New York: Crowell. 1942. Pp. 342. $4.)

CHASE, S. *The road we are traveling 1914-1942.* (New York: Twentieth Century Fund. 1942. Pp. 106. $1.)

DAY, C. *Economic development in Europe; a revision and extension of economic development in modern Europe.* (New York: Macmillan. 1942. Pp. 768. $4.)

DAY, J. *An economic history of Athens under Roman domination.* (New York: Columbia Univ. Press. 1942. Pp. xi, 300. $3.50.)

GATES, C. M., editor. *Readings in Pacific Northwest history; Washington, 1790-1895.* (Seattle: Univ. Bookstore, 4326 University Way. 1941. Pp. 345. $2.50.)

GRAY, L. C. and THOMPSON, E. X. *History of agriculture in the southern United States to 1860.* 2 vols. Carnegie Inst. pub., no. 430, reprint ed. (New York: Peter Smith. 1942. Pp. 1086. $7.50, each vol.)

JOHNSON, V. LER. *The administration of the American Commissariat during the Revolutionary War.* (Allentown, Pa.: Author, c/o Muhlenberg College. 1941. Pp. 238. $3.)

KLINGBERG, F. J. *An appraisal of the Negro in colonial South Carolina; a study in Americanization.* (Washington: Associated Publishers. 1941. Pp. 192. $2.)

LA BOÉTIE, E. DE. *Anti-dictator; the discours sur la servitude volontaire of Étienne de La Boétie.* Rendered into English by HARRY KURZ. (New York: Columbia Univ. Press. Pp. 75. $1.)

A translation of a stirring call to freedom which was written in 1548. It shows how dictators get power and maintain it, and how real power always lies in the hands of the people.

LEWIS, G. E. *The Indiana Company, 1763-1798; a study in eighteenth century frontier land speculation and business venture.* Old Northwest hist. ser. IV. (Glendale, Calif.: A. H. Clark. 1941. Pp. 358. $6.)

LINK, E. P. *Democratic-Republican societies, 1790-1800.* Columbia stud. in Am. culture no. 9. (New York: Columbia Univ. Press. Pp. 268. $2.75.)

MCGRANE, R. C. *The economic development of the American nation.* (Boston: Ginn. 1942. Pp. 712. $3.75.)

MIDDLETON, K. A. *The industrial history of a midwestern town.* Kansas stud. in bus. no. 20. (Lawrence: Univ. of Kansas. 1941. Pp. 89. 50c.)

OVERMAN, W. D., compiler. *Select list of materials on Ohio history in serial publications.* (Columbus: Ohio State Archaeological and Historical Soc. 1941. Pp. 36. 25c.)

PURYEAR, V. J. *France and the Levant, from the Bourbon restoration to the peace of Kutiah.* Univ. of California pub. in hist., vol. 27. (Berkeley: Univ. of California Press. 1941. Pp. 268. $2.50.)

SCHMITT, B. E., editor. *Some historians of modern Europe.* (Chicago: Univ. of Chicago Press. 1942. Pp. 542. $5.)

SHAW, A. H. *The* Plain Dealer, *one hundred years in Cleveland, 1842-1942.* (New York: Knopf. 1942. Pp. 432. $4.)

A history of the famous newspaper.

STEINDORFF, G. and SEELE, K. C. *When Egypt ruled the East.* (Chicago: Univ. of Chicago Press. 1942. Pp. 300. $4.)

STEPHENSON, C. *Mediaeval feudalism.* (Ithaca: Cornell Univ. Press. Pp. 125. $1.25.)

THOMPSON, C. M. *Independent Vermont.* (Boston: Houghton Mifflin. Pp. 589. $4.50.)

An account of the turbulent history of Vermont up to the year 1791, when it was received into the Union.

Norwegian-American studies and records. Vol. 12. (Northfield, Minn.: Norwegian-American Historical Assoc. 1941. Pp. 210. $2.)

A collection of nine articles devoted mainly to social and cultural aspects of Norwegian-American history.

Economic Systems; National Economies

BATES, E. S. *Soviet Asia; progress and problems.* (Forest Hills, N.Y.: Transatlantic Arts. 1942. Pp. 191. $2.75.)

BEHRENDT, R. F. *Economic nationalism in Latin America.* Inter-Americana short papers, 1. (Albuquerque: School of Inter-American Affairs, Univ. of New Mexico. 1941. Pp. 22. 20c.)

BURNHAM, J. and others. *What future for free enterprise?* America's town meeting of the air, vol. 7, no. 16. (New York: Columbia Univ. Press. Pp. 31. 10c.)

BUTLER, R. D'O. *The roots of national socialism.* (New York: Dutton. Pp. 304. $3.)

A critical survey of German thought and the German outlook on society from 1783 to the advent of national socialism in 1933, showing how the present nazi philosophy is due to the rise of Prussia as the controlling force in German life.

CHIPMAN, S. *Democracy in action; a study in social science.* Edited by CLAUDE T. RICHARDS; Preface by HOWARD E. WILSON. (Boston: Moore Pub. Co. 1942. Pp. 126. $1.00; paper, 50c.)

CLARK, S. D. *The social development of Canada.* (Toronto: Univ. of Toronto Press. 1942. Pp. 494. $4.)

COOLE, W. W. and POTTER, M. F., editors. *Thus speaks Germany.* Foreword by HAMILTON FISH ARMSTRONG. (New York: Harper. 1942. Pp. 431. $3.50.)

DAWSON, R. M., editor. *Problems of modern government.* Pol. econ. ser. (Toronto: Univ. of Toronto. 1942. $2.)

Contents: "Foreword" by H. J. Cody; "Introduction," by R. M. Dawson; "The Present Crisis of Constitutionalism," by C. H. McIlwain; "Democratic Possibilities in a Totalitarian World," by H. McD. Clokie; "The Impact of the War on Canadian Political Institutions," by R. M. Dawson; "Taking Stock of Federalism in the United States," by A. W. MacMahon; "The Federal Dilemma," by J. A. Corry; "Canada and the Balance of World Power," by R. A. MacKay; "The Economic Activity of the State in the Dominions," by A. Brady.

COUSINS, N. *The good inheritance; the democratic chance.* (New York: Coward-McCann. 1942. Pp. 328. $3.)

A comparison between ancient Greek democracy and the American way by the editor of the *Saturday Review of Literature.*

EMERSON, R., MILLS, L. A., and THOMPSON, V. *Government and nationalism in southeast Asia.* I.P.R. inquiry ser. (New York: Inst. of Pacific Rel. 1942. Pp. xiii, 242. $2.)

FARAGO, L., editor. *The Axis grand strategy; blueprints for the total war.* (New York: Farrar and Rinehart. 1942. Pp. 623. $3.75.)

The military and political plans of the Axis are revealed in the words of German spokesmen in this collection of excerpts from books, articles, and speeches by influential leaders on Hitler's military, economic, and ideological staff.

GALLOWAY, G. B. *Postwar planning in the United States.* (New York: Twentieth Century Fund. 1942. Pp. xi, 158. Paper, 60c.)

"This volume describes the work of 35 government agencies, 33 private agencies, 11 industrial and financial organizations, 16 trade associations and 7 rail, highway, water and other transportation agencies now actively engaged in post-war planning research."

HASS, E. *The Americanism of socialism.* (New York: New York Labor News Co. 1941. Pp. 45. 5c.)

KINGSLEY, J. D. and PETEGORSKY, D. W. *Strategy for democracy.* (New York: Longmans Green. 1942. Pp. ix, 342. $3.)

DELEON, D. *Capitalism means war.* (New York: New York Labor News Co. 1941. Pp. 32. 5c.)

MACCORMAC, J. *America and world mastery; the future of the United States, Canada, and the British Empire.* (New York: Duell, Sloan and Pearce. 1942. Pp. 338. $2.75.)

Based upon the contention that America must take an active part in the ordering of world affairs after the war. In this program, coöperation with Great Britain will be a predominant factor.

MACDONALD, A. F. *Government of the Argentine Republic.* (New York: Crowell. 1942. Pp. 488. $3.75.)

MILL, J. S. *On social freedom.* Reprinted from the *Oxford and Cambridge Review,* June, 1907. Introduction by DOROTHY FOSDICK. (New York: Columbia Univ. Press. 1941. Pp. 69. $1.)

MISSHIMA, Y. and GOTO, T. *A Japanese view of Outer Mongolia, being a condensed translation of* The Outer Mongolian People's Republic. Translated and summarized from the Japanese *by* ANDREW J. GRAJDANZEV. (New York: Inst. of Pacific Rel. 1942. Pp. 66. 50c.)

MITCHELL, K. L. *Industrialization of the western Pacific.* Inquiry ser.: Econ. survey of Pacific area, pt. 3. (New York: Inst. of Pacific Rel. 1942. Pp. xvii, 317. $2.50.)

———. *Japan's industrial strength.* (New York: Knopf. 1942. Pp. 159. $1.50.)

NEF, J. U. *The United States and civilization.* Charles R. Walgreen Found. lectures. (Chicago: Univ. of Chicago Press. 1942. Pp. 439. $3.)

PORTER, C. *Crisis in the Philippines.* (New York: Knopf. 1942. $1.)

ROBINSON, H., and others. *Toward international organization.* Preface by E. H. WILKINS. (New York: Harper. 1942. Pp. viii, 218. $2.)

SHEPHERD, J. *Industry in southeast Asia, a survey of southeast Asia.* I.P.R. internat. research ser. (New York: Inst. of Pacific Rel. 1942. Pp. 133. 75c.)

TRACHTENBERG, A., editor. *V. I. Lenin, collected works,* Vol. XIX, 1916-1917. Translated by MOISSAYE J. OLGIN. (New York: Internat. Pubs. 1942. Pp. 463.)

TREND, J. B. *South America, with Mexico and Central America.* World to-day. (New York: Oxford Univ. Press. 1942. Pp. 128. $1.)

A brief survey of the history and culture of the Latin-American countries.

UPHAM, T. C. *Total democracy; the new constitution for the United States.* (New York: Carlyle House. 1941. Pp. 119. $1.)

WETTERAUER, G. *Story of Canada, our northern neighbor.* (Philadelphia: F. A. Davis. 1941. Pp. 77. 40c.)

YUGOW, A. *Russia's economic front for war and peace; an appraisal of the three five-year plans.* Translated from the Russian by N. I. and M. STONE. (New York: Harper. Pp. 288. $3.)

Revista de conselho nacional do trabalho. (Rio de Janeiro: Imprensa Nacional. 1941. Pp. 237.)

Statistics; Economic Mathematics; Accounting

DODD, S. C. *Dimensions of society.* (New York: Macmillan. 1942. Pp. 944. $12.)

HARTKEMEIER, H. P. *Principles of punch-card machine operation.* (New York: Crowell. 1942. Pp. 283. $3.25.)

How to operate punch-card, tabulating, and alphabetic accounting machines.

JACKSON, J. H. *Elements of accounting; a pathfinder course.* (Los Angeles: Charles R. Hadley Co., 330 N. Los Angeles St. 1941. Pp. 446. $3.60.)

RATNER, S. *American taxation; its history as a social force in democracy.* (New York: Norton. 1942. Pp. 561. $4.50.)

SEIDEMANN, H. P. *Curtailment of non-defense expenditures.* Brookings Inst. pamph. no. 30. (Washington: Brookings Inst. 1941. Pp. 61. 25c.)

SHULTZ, W. J. *American public finance.* 3rd ed. (New York: Prentice-Hall. 1942. Pp. xxiii, 874. Trade ed., $6; school, $4.50.)

VOGEL, M. and BERGNER, R. W., editors. *Manual of federal income and excess profits tax procedure, 1942.* 28th annual ed. (Chicago: LaSalle Extension University. 1942. Pp. iv, 315.)

Budget of the United States government for the fiscal year ending June 30, 1943. (Washington: Budget Bureau. 1942. $2.25.)

Budget of the United States government for the fiscal year ending June 30, 1943, budget message of the President and summary budget statements. (Washington: Budget Bureau. 1942. Various paging. 40c.)

Financing the war; symposium conducted by the Tax Institute, December 1-2, 1941, Philadelphia. (Philadelphia: Tax Institute. 1942. Pp. 366. $2.50.)

Income, estate and tax provisions of the Internal Revenue Code, as amended to October 1, 1941. (Chicago: Commerce Clearing House. 1941. Pp. 371. $1.)

Report on nondefense expenditures in the 1942 budget; letter from Director, Bureau of Budget, transmitting to the chairman of the Committee on Finance, U. S. Senate, pursuant to resolution of committee, report relative to reductions in expenditures for the fiscal year ending June 30, 1942, and to changes in classification between nondefense and defense expenditures since the fiscal year 1940, Oct. 15, 1941. (Washington: Finance Committee, Senate. 1941. Pp. 21. 5c.)

Research in public budget administration, an outline of suggested research topics. (New York: Committee on Public Admin., Social Science Research Council. 1941. Pp. 37. 50c.)

Secretary of the Treasury: annual report on the state of the finances for the fiscal year ended June 30, 1941. (Washington: Treasury Dept. 1942. Pp. 716. $1.)

Third supplemental defense appropriation, 1942: hearings, 77th Cong., 1st sess., on H. R. 6159, bill making supplemental appropriations for national defense for fiscal years ending June 30, 1942, and June 30, 1943, and for other purposes. (Washington: Appropriations Committee, Senate. 1941. Pp. 355. 35c.)

Third supplemental defense appropriation, 1942: hearings, 77th Cong., 1st sess., on the third supplemental national defense appropriation bill for 1942. Part 1. *General appropriations.* Part 2. *Military and Naval Establishments and lend-lease.* (Washington: Appropriations Committee, House. 1941. Pp. 636; 265. 65c; 25c.)

United States master tax guide, 1942. (Chicago: Commerce Clearing House. 1942. Pp. 288. $1.)

Money and Banking; Short-Term Credit

BLASER, A. F., JR. *The Federal Reserve Bank of Cleveland.* (New York: Columbia Univ. Press. 1942. Pp. xxviii, 306. $3.50.)

CHAPMAN, J. M. and WESTERFIELD, R. B. *Branch banking; its historical and theoretical position in America and abroad.* Special chapters by G. E. JACKSON and M. MEGRAH. (New York: Harper. 1942. Pp. xi, 431. $4.50.)

REED, H. L. *Money, currency and banking.* (New York: McGraw-Hill. 1942. Pp. viii, 522. $3.75.)

Annual report of the commissioner of banking and insurance, State of New Jersey, relative to savings banks, trust companies and state banks of discount and deposit, credit unions, provident loan associations, small loan brokers and pawnbrokers, for the year ending December 31st, 1940. (State of New Jersey. 1941. Pp. xxvii, 105.)

Federal Deposit Insurance Corporation: report to insured banks, December 31, 1941. (Washington: Federal Deposit Insurance Corporation. 1942. Pp. 6.)

Management appraises the credit union. Farm Credit Admin. circular 28. (Washington: Supt. Docs. 1941. Pp. 32. 10c.)

Gives the opinions of employers in whose plants, offices, and stores employees' federal credit unions have functioned for a considerable period of time.

International Trade, Finance and Economic Policy

ABEND, H. *Ramparts of the Pacific.* (New York: Doubleday. 1942. $3.)

BRADLEY, A. *Trans-Pacific relations of Latin America.* I.P.R. internat. research ser. (New York: Inst. of Pacific Rel. 1942. Pp. 120. $1.)

BRODIE, F., editor. *Our Far Eastern record.* Vol. 2. *A reference digest on American policy.* Far Eastern pamph., no. 4. (New York: Inst. of Pacific Rel. Pp. 78. 15c.)

CAVERS, D. F., editor. *Hemispheric trade.* Law and contemporary problems, vol. 8, no. 4. (Durham, N.C.: Law and Contemporary Problems. 1942. Pp. 148. $1.)

DAVIS, H. O. *America's trade equality policy.* (Washington: Am. Council on Pub. Affairs. 1942. Pp. 137. $3.)

GREENE, K. R. C. and PHILLIPS, J. D. *Transportation and foreign trade.* Econ. survey of the Pacific area, pt. 2. (New York: Inst. of Pacific Rel. 1942. Pp. 222. $2.)

Information on the conditions and development of transportation in the Pacific countries, together with a review and statistical summary of foreign trade in the Pacific area during the past decade.

HAAS, W. H. *Outposts of defense.* Special pub. policy pamph. (Chicago: Univ. of Chicago Press. 1942. Pp. x, 82. 50c.)

HARGRAVE, J. *Montagu Norman.* (New York: Greystone Press. 1942. Pp. 247. $2.75.)

The financial policies of Montagu Norman, Governor of the Bank of England, as they developed during the rise of Hitler are described and censured in this full-length biography.

NEVINS, A. *America in world affairs.* World to-day. (New York: Oxford Univ. Press. Pp. 140. $1.)

A digest of the recent history of American foreign relations, originally prepared for British readers.

RALSTON, J. H. *A quest for international order.* (Washington: J. Byrne and Co. 1941. Pp. 205. $2.)

SPYKMAN, N. J. *America's strategy in world politics; the United States and the balance of power.* Inst. of Internat. stud., Yale Univ. (New York: Harcourt Brace. 1942. Pp. 500. $3.75.)

TORPATS, J. *Economic basis for world peace.* (New York: John Felsberg. 1941. Pp. 222. $3.)

DE WILDE, J. C. and WOOD, B. *U. S. trade ties with Argentina.* Foreign policy repts., vol. 17, no. 18. (New York: Foreign Policy Assoc. 1941. Pp. 11. 25c.)

WOYTINSKY, W. S. *Three aspects of labor dynamics.* (Washington: Committee on Social Security, Social Science Research Council. 1942. Pp. xiv, 249. $2.50.)

Secretary of Labor: annual report for the fiscal year ended June 30, 1941. (Washington: Labor Dept. 1942. Pp. 165. 20c.)

Collective bargaining contracts. (Washington: Bur. of Nat. Affairs, Inc. 1942. Pp. 740. $7.50.)

This handbook discusses the techniques of negotiation and administration with topical classification of clauses.

Conciliation act of 1941: hearings, 77th Cong., 1st sess., on S. 683, to expedite the national-defense program by providing a method for the settlement of labor disputes

in defense industries without resort to hasty strikes and lock-outs, May 6 to 29, 1941. (Washington: Education and Labor Committee, Senate. 1941. Pp. 351. 30c.)

Employment agencies: hearings, 77th Cong., 1st sess., on H. R. 5510, to regulate private employment agencies engaged in interstate commerce, Nov. 17, 19, 21, 1941. (Washington: Labor Committee, House. 1941. Pp. 272. 25c.)

Employment and wages of covered workers in state unemployment compensation systems—1939. Employment Security memo. no. 17. (Washington: Research and Statistics Division, Social Security Board. 1941. Pp. xiii, 404.)

Employment security in Ohio, 1940; a report of activities of the Bureau of Unemployment Compensation. (Columbus; Ohio Bur. of Unemployment Compensation. 1941. Pp. 94.)

Handbook of federal labor legislation: Part 2, *Labor laws of general application.* Labor standards div., bull. 39, pt. 2. (Washington: Supt. Docs. 1941. Pp. 150. 30c.)

Labour in the colonies, some current problems. Reports submitted to the Labour Committee of the Fabian Colonial Bureau. Research ser. no. 61. (London: Fabian Society. 1942. Pp. 47. 1*s*.)

Reports of committees and resolutions adopted by Eighth National Conference on Labor Legislation, Nov. 12, 13 and 14, 1941. Labor standards div., bull. 52-A. (Washington: Supt. Docs. 1941. Pp. 23. 10c.)

National Mediation Board; seventh annual report, including Report of National Railroad Adjustment Board, fiscal year ended June 30, 1941. (Washington: Nat. Mediation Board. 1941. Pp. 87. 20c.)

Strikes in defense industries, supplementary information to accompany S. Doc. 52 (77th Cong., 1st sess.); statement showing certain basic data for formulation of policy toward strikes in defense industries. 77th Cong., 1st sess., S. Doc. 147. (Washington: Supt. Docs. 1941. Pp. 35. 10c.)

Workmen's protective legislation in Poland; twenty years co-operation with the International Labor Organization. (New York: Am. Friends of Polish Democracy. 1941. Pp. 48.)

Social Insurance; Relief; Pensions; Public Welfare

James, A. W. *The state becomes a social worker; an administrative interpretation.* (Richmond: Garrett and Massie. 1942. Pp. 382. $3.)

Approaches to Social Security, an international survey. Stud. and repts. ser. M (social insurance) no. 18. (Montreal: Internat. Labour Office. 1942. Pp. iii, 100. 50c.)

Federal Works Agency: second annual report, 1941. (Washington: Supt. Docs. [1942.] Pp. v, 473. 65c.)

Old-age pensions: hearings, 77th Cong., 1st sess., on S. 1932, to amend the Social Security act to provide for general pensions, and for other purposes, Dec. 1, 2, and 15, 1941. (Washington: Finance Committee, Senate. 1941. Pp. 147. 15c.)

Pennsylvania public assistance statistics; summary, 1932-1940. (Harrisburg: Dept. of Public Assistance, Temporary Bldg., no. 4, Capitol Park. 1941. Pp. 91.)

Post-defense planning: hearings, 77th Cong., 1st sess., on S. 1617, to amend the Employment Stabilization act of 1931; S. 1833, to promote the general welfare of the nation by providing work on public projects to persons in need of employment, and for other purposes; S. Res. 178, creating a select committee to investigate unemployment and relief, Nov. 3, 4, 5, 6, and 7, 1941. (Washington: Education and Labor Committee, Senate. 1941. Pp. 165. 20c.)

Public assistance, 1940. Pub. assistance rept. 1. (Washington: Social Security Board. 1941. Pp. 41. 15c.)

Social security in wartime and after; statement and recommendations by 68 of the nation's leading experts and students of the problem. (New York: Am. Assoc. for Social Security. 1942. Pp. 55. 25c.)

Social security yearbook, 1940. (Washington: Social Security Board. 1941. Pp. xix, 347. 70c.)

Socio-economic and employment status of urban youth in the United States, 1935-36. Pub. health bull. 273. (Washington: Public Health Service. 1941. Pp. 58. 15c.).

United States Employees' Compensation Commission: twenty-fifth annual report, July 1, 1940 to June 30, 1941. (Washington: Employees' Compensation Commission. 1941. Pp. 78. 15c.)

Youth and the future; the general report of the American Youth Commission. Foreword by Floyd W. Reeves. Introduction by Owen D. Young. (Washington: Am. Council on Educ. Pp. 315. $2.50.)

Consumption; Income Distribution; Coöperation

Bercaw, L. O. and Hennefrund, H. E., compilers. *Distribution of farm income by size, a selected bibliography.* Agric. econ. bibliog. no. 96. (Washington: Bur. of Agric. Econ., Agriculture Dept. 1942. Pp. iv, 103.)

Dale, E. and Vernon, N. *Consumer education, an annotated bibliography.* Ser. 1, vol. 1, no. 3. (Columbus: Bur. of Educ. research, Ohio State Univ.; Columbia, Mo.: Inst. for Consumer Educ. 1941. Pp. 35 25c.)

Floyd, O. R. and Kinney, L. B. *Using dollars and sense: consumer economics.* Newson soc. stud. ser. (New York: Newson and Co. 1942. Pp. 314. $1.40.)

Hamblen, S. B. and Zimmerman, G. F. *How to spend wisely.* (New York: Harper. 1942. Pp. 384. $2.50.)
Previously published under the title, *Wise Spending.*

Kennedy, A. and Vaughn, C. *Consumer economics workbook.* (Peoria: Manual Arts Press. 1941. Pp. 112. 76c.)

Moffett, C. W. *More for your money.* Public affairs pamph., no. 63; consumer ser. no. 4. (New York: Public Affairs Committee. 1942. Pp. 31. 10c.)

Tereshtenko, V. J. *Coöperative education.* (New York: Federal Works Agency. 1941. Pp. xxiii, 363.)

Williams, F. M. and Hanson, A. C. *Money disbursements of wage earners and clerical workers 1934-36, summary volume.* Bur. of Labor Stat. bull. 638. (Washington: U. S. Dept. of Labor. 1941. Pp. ix, 402. 55c.)

Consumer education for life problems; proceedings of the third national Conference on consumer education held at Stephens College, April 7-9, 1941. Bull. no. 3. (Columbia, Mo.: Inst. for Consumer Educ., Stephens Coll. 1941. Pp. 201. $1.50.)

Population; Migration; Vital Statistics

Cowgill, D. O. *Mobile homes; a study of trailer life.* (Washington: Am. Council on Pub. Affairs. 1941. Pp. 127. $2.)

McWilliams, C. *Ill fares the land; migrants and migratory labor in the United States.* (Boston: Little, Brown. 1942. Pp. 419. $3.)

Pelzer, K. J. *Population and land utilization.* Econ. survey of the Pacific area, pt. 1. (New York: Inst. of Pacific Rel. 1942. Pp. 230. $2.)

Information on the basic trends of population and land use in the countries of the Pacific.

Population facts for planning Chicago. (Chicago: Chicago Plan Commission. 1942. Pp. viii, 32.)

Vital statistics of the United States, 1939: Part 1, *Natality and mortality data for the United States tabulated by place of occurrence with supplemental tables for Hawaii, Puerto Rico, and the Virgin Islands.* (Washington: Census Bureau. 1941. Pp. 531. $1.50.)

Unclassified Items

ADAMS, E. T., and others. *The American idea.* (New York: Harper. 1942. Pp. 278. $2.50.)

History, government, economics, science, art, literature, education, religion, and philosophy are discussed in relation to democracy by nine members of the faculty of Colgate University.

BANNING, M. C. *Women for defense.* (New York: Duell, Sloan and Pearce. 1942. Pp. 255. $2.50.)

BLAICH, T. P., and others. *The challenge of democracy.* (New York: Harper. 1942. Pp. 609. $2.20.)

BURGIN, M., editor. *Handbook of Latin American studies: 1940, no. 6: a selective guide to the material published in 1940 on anthropology, archives, art, economics, education, folklore, geography, government, history, international relations, language and literature, law, libraries, music, and philosophy.* (Cambridge: Harvard Univ. Press for Am. Council of Learned Societies. 1941. Pp. 587. $4.)

The handbook is a masterpiece of bibliographical research. The entries are classified as to content and each entry is numbered for cross-reference purposes. Published materials in the field of economics have been canvassed and edited by Leland H. Jenks, Frank W. Fetter, and Roberto Simonsen. Each article entered in the bibliography is summarized in a sentence or two.

FITZPATRICK, P. J. and DIRKSEN, C. F. *Bibliography of economic books and pamphlets by Catholic authors, 1891-1941.* Stud. in econ., vol. 7. (Washington: Catholic Univ. of America Press. 1941. Pp. xi, 55.)

KUHLMAN, A. F., editor. *The development of university centers in the South.* Papers presented at the dedication of the Joint University Library, December 5 and 6, 1941, Nashville, Tennessee. (Nashville: Peabody Press and Vanderbilt Univ. Press for Joint Univ. Libraries. 1942. Pp. 128.)

PLENN, A. *List of Latin American serials; a survey of exchanges available in U. S. libraries.* Stud. of A.L.A. Committee on lib. coöp. with Latin America, no. 1. (Chicago: Am. Lib. Assoc. 1941. Pp. 70.)

Studies in the history of culture; the discipline of the humanities. Am. Council of Learned Societies. (New York: Modern Language Assoc. 1942. Pp. 339. $3.)

Twenty-one papers in honor of Waldo Gifford Leland, director of the American Council of Learned Societies. Edited by Dr. Percy W. Long.

NOTES

Editorial Notes—Under present circumstances it is difficult to secure review copies, or even to know of the existence, of books published in foreign countries which may be of interest to readers of the *Review*. Several persons have assisted by voluntarily calling attention to foreign books, and in a few instances by submitting unsolicited reviews. Assistance of this sort is much appreciated, and I hope that others will serve the readers of the *Review* in the same way.

The preparation of the list of articles from current periodicals which appears in each number of the *Review* presents an almost insoluble problem of selection. The listing has been curtailed by the omission of many short articles from dubitably scientific periodicals, and has been extended to include more articles from the law quarterlies. The most difficult area of choice is that of the numerous periodicals dealing with specialized fields which are of interest to various groups of economists, such as accounting, taxation, marketing, insurance, agricultural economics, transportation, and industrial management. It is impossible to be exhaustive, so it is necessary to suppose that people with highly specialized interests follow the periodical literature in their own fields and are not dependent on the *Review* as a primary bibliographical source. I hope, however, that persons who find the present listing inadequate for their needs will send in their suggestions for broader coverage.

The *Review* is also receiving a large number of economic and statistical periodicals from Latin America, from which only a very select list of titles is published. A complete list of these periodicals will be published in September, as a guide to economists interested in the economic affairs of Latin America.

Attention is again called to the need of the *Review of Economic Studies* for new American subscribers to take the place of continental European subscribers. In spite of the influential part it has played in the development of economic analysis in recent years, for some reason it has had a very small number of paid-up American subscribers. Checks for the subscription price of $2.00 should be sent to Paul M. Sweezy, 10 Forest Street, Cambridge, Mass.

An inquiry has recently been sent to all institutions known to grant doctor's degrees in economics, requesting data concerning candidates for the thesis list to be published in September. If any institution having doctoral candidates has not received this inquiry, it would be appreciated if it will write this office at once.

All over the United States, and especially in Washington, small groups of economists are engaged in intensive study and discussion of problems of economic analysis and public policy. But for some reason the results of this forward-looking thought do not readily reach the economic journals. "The Inflationary Gap," for example, on which a two-man symposium is published in this number, has been actively under discussion for over a year. Problems of general rationing, on which it is hoped to publish a symposium in September, have similarly escaped the printed page. It will be a substantial aid in getting such subjects promptly into print for the general benefit of economists if persons immediately concerned will call them to my attention and suggest a panel of competent persons to discuss them.—P.T.H.

The American Council of Learned Societies is sponsoring a program of intensive instruction in languages designed to provide opportunity for Americans trained in the usual university disciplines—history, economics, engineering, journalism, the physical and mathematical sciences, etc.—to add to their competences control of one of the unusual languages likely to be necessary in the war effort. Those interested can learn more of the program by writing to The Intensive Language Program, American Council of Learned Societies, 1219 Sixteenth Street, N.W., Washington, D.C.

The Science-Technology group of the national Special Libraries Association has undertaken to compile, for the benefit of users of the Russian scientific and technical periodicals, current or otherwise, a complete list of the holdings of such periodicals in all the libraries of the United States and Canada, as far as possible, whether personal, institutional or industrial. Owners and librarians in charge of such materials are asked to send in on 3 by 5 inch slips the following information: (1) title of periodical, transliterated according to A.L.A. or Library of Congress rules; (2) holdings in volume numbers and years exact to month and issue number; (3) is it received currently? (4) can the periodicals be borrowed? photostatted? microfilmed? (5) subject or subjects to which this periodical is devoted; (6) former titles, if any, in chronological order and on the other side of the slip. This information should be sent to Miss Nathalie D. Frank, 512 West 162nd Street, New York, New York.

Jessica B. Peixotto, professor emeritus at the University of California, died in October.

Appointments and Resignations

J. Russell Andrus, associate professor of economics at the University of Redlands, is on leave of absence and is now working as economic research analyst for the Far Eastern Section of the Bureau of Foreign and Domestic Commerce, Washington, D.C.

James W. Angell, professor of economics at Columbia University, was granted a leave of absence during the second semester of 1941-1942 to accept an appointment in Washington, D.C.

Roy Ashmen, instructor in accounting at Louisiana State University, is now a lieutenant in the Naval Reserve and is stationed at Jacksonville, Florida.

Rollin S. Atwood of the University of Florida has been granted a leave of absence to become economic analyst attached to the United States Embassy at Quito, Ecuador.

William Bade, a New York University-Tax Foundation Fellow, has resigned to accept a position with the War Production Board in Washington, D.C.

Marvin A. Bacon of the University of Michigan is now in the Rent Division of the Office of Price Administration.

Theodore N. Beckman of Ohio State University is now serving on a part-time basis as chief consultant of the Division of Civilian Supply, War Production Board.

M. M. Bober has been granted a leave of absence from Lawrence College to join the staff of the Office of Price Administration, Washington, D.C.

Gladys Boone has been appointed chairman of the new Division of Social Studies at Sweet Briar College, which combines the department of economics and sociology and the department of history and government.

Daniel Borth, professor of accounting in the College of Commerce and auditor of Louisiana State University, joined the Army in February with the rank of Major in the Quartermaster Corps and is now stationed in Washington, D.C.

D. O. Bowman, instructor at the University of Michigan, has been given leave for the duration of the emergency to work in the Chicago office of the Office of Price Administration.

Benjamin F. Brooks, professor of economics at Butler University, has been granted leave of absence to become a liaison officer with the Civil Service Commission in Washington, D.C.

R. P. Brooks, dean of the College of Business Administration, University of Georgia, is regional price executive of the Office of Price Administration in the Atlantic office.

J. Douglas Brown, who has returned to Princeton University from the War Production Board, is serving as a consultant to the War Department on man-power policy.

Roy J. Bullock has been promoted to associate professor of political economy at the Johns Hopkins University.

Malcolm Burnside has been given a leave of absence by the American Telephone and Telegraph Company and has entered active service as a Naval Reserve officer.

Henry Chen, junior assistant in the department of economics of the School of Commerce, New York University, has been appointed a representative of the Ministry of Economics of the Republic of China.

Morris Chertkov has received an appointment in the legal division of the War Production Board, at Washington, D.C., and is on leave from the University of Washington.

Howard E. Cooper has been promoted to associate professor of political economy at the Johns Hopkins University.

R. S. Cornish, formerly of Waynesburg College, has joined the staff of the College of Business Administration at the University of Georgia as an associate professor of economics.

Virgil Cover has returned to Washington from Dallas, where he was regional business consultant for the Department of Commerce, to assume the position of transportation economist in the Bureau of Foreign and Domestic Commerce.

Earl C. Crockett, professor of economics at the University of Colorado, has been granted a leave of absence to work with the War Production Board, Washington, D.C.

Walter A. Chudnowsky has been appointed an instructor in economics at Columbia University after having served as a research associate with the National Bureau of Economic Research during the past year. He is also serving as a consultant in the Division of Research of the Office of Price Administration.

Amando M. Dalissay is now a junior business economist with the Office of Price Administration.

Paul T. David has resigned as associate director for research and chief economist of the American Youth Commission of the American Council on Education to accept a position as a chief statistical analyst in the Fiscal Division of the United States Bureau of the Budget. He was formerly secretary of the President's Advisory Committee on Education.

Leonard A. Drake, who has been in government service for some time, carrying on economic research work in other agencies, has been appointed regional business consultant of the Department of Commerce, and is stationed at Philadelphia.

William E. Dunkman is on leave from the University of Rochester while working in the Division of Civilian Supply of the War Production Board.

Robert P. Eastwood has been promoted from instructor to assistant professor of business statistics in the Columbia University School of Business.

Clarence W. Efroymson, associate professor of economics at Butler University, has been

granted leave of absence while working with the Office of Price Administration, Washington, D.C.

Wilford J. Eiteman of Duke University is on leave of absence and is at present in the Office of Price Administration in the Nonferrous Materials Division.

George Heberton Evans, Jr., has been promoted to professor of political economy at the Johns Hopkins University.

J. Wesley Fly of the University of Florida, who held an officer's commission in the Reserve Corps, has been granted a leave of absence upon being called into active service.

John L. Fulmer, associate professor of rural economics at the University of Virginia, has been given a leave of absence and is now a Captain in the Army.

Mary Gilson of the University of Chicago gave a course in industrial relations at Wellesley College during the second semester of 1941-1942.

Henry Glass, a former junior assistant in the department of economics of the School of Commerce, New York University, is now with the Office of Price Administration, Washington, D.C.

Joseph Gordon, formerly assistant manager of the research department of Merrill, Lynch, Pierce, Fenner and Beane, New York, is now chief of the Import Priorities Section of the War Production Board.

Robert E. Graham, Jr., acting associate professor of rural economics at the University of Virginia, was called into active service in February and is now a Lieutenant at Fort McClellan, Alabama.

William Haber, professor of economics at the University of Michigan, was given leave for the second semester to assist the Director of the Budget in Washington, in coördinating various pension plans.

George G. Hagedorn of the Lehman Corporation joined the Army in March.

Everett E. Hagen of Michigan State College is now serving with the National Resources Planning Board, Washington, D.C.

James K. Hall of the University of Washington has been appointed price executive with the Seattle office of the Office of Price Administration and will be on leave until September.

Earl J. Hamilton of Duke University will spend four months, June through September, in the archives of Colombia, Guatemala, and Mexico, gathering material for a book on the economic background of the Monroe Doctrine.

Tom Hancock, instructor in economics at the University of Kansas, entered the Army in February.

Robert W. Harbeson of Rutgers University has been appointed economic consultant to the New Jersey Rationing Administration.

David Harrison of the department of economics of Ohio State University is serving as senior economist in the Steel Section of the Office of Price Administration.

Everett D. Hawkins, associate professor of economics, has been granted leave of absence from Mount Holyoke College extending through 1942-43, in order to accept a special assignment with the Office of Price Administration.

Carl H. Henrikson, Jr., regional business consultant of the Department of Commerce at Philadelphia, has been transferred to New York, where he is at the Department's regional office, 500 Fifth Avenue.

William W. Hewett, professor of economics at the University of Cincinnati, was granted a leave from April 20 to June 30, to accept a special assignment with the Tax Research Division of the Treasury Department.

Frederick R. Hoisington, Jr., of the International Telephone and Telegraph Corporation, has been appointed principal economist with the Alien Property Division of the Department of Justice.

Edgar M. Hoover, Jr., associate professor of economics at the University of Michigan, is on leave of absence and will work through the summer in the Fuels Division of the Office of Price Administration in Washington.

M. H. Hornbeak, formerly associate professor of business administration at Louisiana State University and lately vice president of the Louisiana National Bank, Baton Rouge, entered the army in March as a Lieutenant in the Quartermaster Corps, stationed in Washington.

Clifford James, professor of economics, is on leave of absence from Ohio State University to serve as regional price executive in the Office of Price Administration, in Cleveland.

Lloyd Johnson has been appointed instructor in accounting at the University of Florida.

Richard B. Johnson, assistant professor of business and economics at the University of Arkansas, has resigned to assume the position of regional business consultant of the Department of Commerce, stationed at Dallas. Before going to Dallas, he spent considerable time in Washington, becoming acquainted with the work of a number of war agencies.

J. Maynard Keech of Duke University is on leave and is at present with the Civil Service Commission.

Marshall D. Ketchum, recently advanced from assistant to associate professor of economics at the College of Commerce, University of Kentucky, will be professorial lecturer in finance in the School of Business, University of Chicago, during the summer quarter of 1942.

Will F. Kissick, chief economist of the Coöperative Business Research Station established jointly by the University of Minnesota and the Department of Commerce at Minneapolis, has been transferred to the regional office in Minneapolis as acting regional business consultant.

Harold D. Koontz, assistant professor of economics at Colgate University, has been named economic consultant to the chief of the Machinery and Equipment Section of the Office of Price Administration.

Mabel S. Lewis has taken a position with the Post-War Division of the Bureau of Labor Statistics, Washington, D.C.

Shaw Livermore, professor of economics, has been on leave from the University of Buffalo since April, 1941, to serve in the Priorities Division of the War Production Board.

Clarence D. Long has been promoted to associate professor of economics at Wesleyan University and granted a renewal of his leave of absence. During 1941-42, he has been preparing a book on the history of unemployment in the United States, with the support of a Guggenheim Fellowship and a membership in the Institute for Advanced Study at Princeton. He will continue this work during 1942-43 under the same auspices.

Hastings Lyon is retiring from the Columbia University School of Business at the end of the 1941-42 academic year.

Donald H. Mackenzie, associate professor at the University of Washington, has been acting as an examiner for the National War Labor Board in matters affecting waterfront labor relations in the Puget Sound area.

Lewis F. Manly has been named acting chairman of the department of economics and sociology at Tufts College.

Donald Marsh, instructor in economics in Barnard College, Columbia University, will teach introductory economics in the new summer session for the acceleration of the college course for women undergraduates.

Boyce F. Martin, dean of the School of Business Administration at Emory University, has resigned to take a position with the Louisville Cement Company.

Carl Marzani, senior assistant and part-time instructor in the department of economics of the School of Commerce, New York University, has resigned to accept a position with the Coördinator of Information in Washington, D.C.

Walter J. Matherly, dean of the College of Business Administration, University of Florida, has been appointed a director of the Jacksonville branch of the Federal Reserve Bank of Atlanta.

Orville J. McDiarmid, assistant professor of economics and business administration at the College of William and Mary, is on leave for the second semester of 1941-42 and is

now employed as economist in the Post-War Division of the Bureau of Labor Statistics.

F. Eugene Melder, associate professor of economics and sociology at Clark University, has been awarded a grant-in-aid by the Social Science Research Council for research on the impact of interstate trade barriers.

B. J. Merriam, instructor in economics at the University of Kansas, resigned at the end of the first semester of 1941-42 to accept employment with the Transportation Board, Washington, D.C.

Nicholas Mirkovich, formerly at the department of economics, University of California, resigned from the staff of the International Secretariat of the Institute of Pacific Relations to join the Yugoslav Government in London as chief of the newly created Office of Reconstruction and Economic Affairs, and also to act as deputy chairman of the Economic Division of the Eastern and Central European Planning Board, a joint planning body of the governments of Poland, Czechoslovakia, Yugoslavia and Greece.

Robert C. Mizell, director of university development at Emory University, has been appointed acting dean of the School of Business Administration.

Jacob L. Mosak of the University of Chicago has been given a leave of absence and is now senior economist in the Office of Price Administration.

Peter F. Palmer, instructor in economics at the University of Kansas, resigned at the end of the first semester of 1941-42 to accept an appointment as assistant professor of economics at Marquette University.

Harlow S. Person is retiring from the School of Business Administration of Columbia University in June.

Charles F. Phillips, professor of economics at Colgate University, has been named associate price executive in the Rubber Division of the Office of Price Administration. He was formerly a marketing consultant for the Office.

Earl Powers, who held an officer's commission in the Reserve Corps, has been granted a leave of absence by the University of Florida, upon being called to active duty.

L. B. Raisty, head of the department of public finance at the University of Georgia, is in charge of the administration of installment buying regulations at the Federal Reserve Bank of Atlanta.

Joseph S. Ransmeier, instructor in economics at Vanderbilt University, is now working in Washington at the Office of Price Administration.

Lloyd G. Reynolds has been promoted to associate professor of political economy at the Johns Hopkins University.

J. H. Richardson, formerly visiting professor at the University of Toronto, has been appointed economic adviser to the Governor of Bermuda.

B. R. Risinger, instructor in business administration and assistant to the dean of the College of Commerce at Louisiana State University, was made purchasing agent of the University in April.

W. R. Roane, instructor in accounting and assistant auditor of Louisiana State University, has been named auditor of the University.

Myron Rosenfield of the New York State Division of State Planning is now employed as an associate economist in the Copper and Brass Section of the Office of Price Administration.

Raymond J. Saulnier, professor of economics at Barnard College, taught monetary economics at Columbia University during the last part of the second semester of 1941-42.

Franklin Scheider, instructor at the College of Business Administration, University of Georgia, is now a reserve officer at Fort Benning.

Melvin J. Segal has been granted a leave of absence from Southern Illinois Normal University to accept a position as chief economist with the Minimum Wage Board of the Government of Puerto Rico.

William H. Shannon, associate professor of accounting at the University of Kansas, has been granted a leave of absence while serving in the Navy, where he holds the rank of Lieutenant in the Supply Corps.

I. Leo Sharfman, professor of economics at the University of Michigan, has been appointed an associate member of the War Labor Board.

Lloyd L. Shaulis, chairman of the department of economics and sociology at Tufts College, has been on leave of absence since February, and is now with the Office of Price Administration.

Edward C. Simmons, who has held a post-doctoral fellowship of the Social Science Research Council, has transferred to the Office of Price Administration in Washington, D.C.

Isidore Singer, formerly of the College of the City of New York and Brooklyn College, has been appointed junior assistant in the department of economics of the School of Commerce, New York University.

Arnold L. Skinner, formerly stationed at the regional office of the Bureau of Foreign and Domestic Commerce in Minneapolis, has joined the Naval Reserve.

R. Elberton Smith, formerly of the department of economics at the University of Denver, is now an economist in the Research and Analysis Section of the War Production Board.

Robert S. Smith of Duke University has received a Guggenheim award and will spend the summer in Mexico, in research on economic history.

Joseph J. Spengler has resumed his teaching duties at Duke University after being on sabbatical leave in the first semester.

Henry W. Speigel of Duquesne University will teach courses in war economics and agricultural policy in the summer session at Michigan State College.

John D. Sumner, professor of economics, has been on leave from the University of Buffalo since June, 1941, and is serving as price executive in the Office of Price Administration.

Glenn W. Sutton of the University of Georgia has been commissioned in the Navy and is located in Rhode Island.

W. A. Tolman is on leave from the University of Kentucky and has accepted a position as regional price economist in the Bureau of Labor Statistics in charge of the Atlanta regional office.

Lawrence W. Towle of Lawrence College was acting professor of economics at the University of Florida for the second semester of 1941-42.

Malcolm D. Taylor has been granted a leave of absence from the University of North Carolina to accept a position with the Civil Service Commission.

Lorie Tarshis, assistant professor of economics at Tufts College, has accepted a position with the Board of Economic Warfare.

Mary Van Brunt taught introductory economics at Barnard College during the second semester of 1941-42.

Charles J. Walsh, assistant professor of economics at the School of Business, Fordham University, has been granted a leave of absence in order to accept a position as business specialist with the Office of Price Administration, Washington, D.C.

Edward C. Welsh is on leave of absence from the department of economics of Ohio State University to serve as principal economist in the Office of Price Administration in Cleveland.

Robert L. Whaley, formerly commercial agent for the Department of Commerce stationed at Detroit, has assumed the position of regional business consultant at St. Louis, following an intensive period of training in Washington, to acquaint him with the work of the federal agencies in St. Louis.

Bayard O. Wheeler, lecturer at the University of Washington, is doing part-time research in the Seattle office of the Bureau of Labor Statistics and in the Seattle office of the Office of Price Administration, where he will be on a full-time basis after June 15.

Joseph A. Yager, formerly teaching fellow at the University of Michigan, is working with the National Resources Planning Board in Washington.

E. L. Zingler of Louisiana State University is on leave until September with the National Resources Planning Board in Dallas.

Entered at the post office at Menasha, Wisconsin, as second class matter. Acceptance for mailing at special rate of postage provided for in the Act of February 28, 1925, embodied in paragraph 4, section 412, P. L. and R., authorized September 13, 1928.

THE EXTENT AND BASES OF MONOPOLY

By GEORGE J. STIGLER

I shall summarize and appraise in this paper material provided by the Temporary National Economic Committee in answer to two basic questions:

1. What are the relative rôles of competition and monopoly in the American economy?
2. What are the leading bases of monopoly?

The discussion of these questions will be highly selective. Obviously no one need apologize for a lack of comprehensiveness in a discussion of approximately thirty-three thousand pages of hearings and monographs. I have gone much further and concentrated attention upon a very few topics in the conviction that an encyclopedic, running commentary would be of little value.

I—The Competitiveness of the Economy

Although several specific T.N.E.C. studies are concerned directly with measures of monopoly or concentration, and although much of the entire investigation can be viewed as an unsystematic investigation of the extent of monopoly,[1] the meaning of the search received little attention. It is not possible here to examine the problem in appropriate detail, but at least a cursory examination is in order.

We may begin by raising a point of terminology. If we mean by competition and monopoly perfect competition and perfect monopoly,[2] obviously neither has ever existed nor will either ever exist. (The frequent criticism of theoretical, and especially classical, economists that they are or were not aware of this fact reveals both a distressing ig-

[1] In the President's Message of April 29, 1938, which led to the T.N.E.C., the recommendations begin, "To meet the situation I have described, there should be a thorough study of the concentration of economic power in American industry and the effect of that concentration upon the decline of competition." (*Investigation of Concentration of Economic Power,* Hearing before Temporary National Economic Committee, December 1938, on Pub. Res. 113 (75th Cong.), Pt. 1, *Economic Prologue* [Washington, Supt. Docs., 1939], p. 189. See also Appendix A, *infra,* p. 125.) The resolution establishing the committee named as its first duty the fulfillment of this and other requests of the President (*ibid.,* p. 192; see also Appendix B, *infra,* p. 129.)

[2] The specifications of perfect competition are well known (see F. H. Knight, *Risk, Uncertainty and Profit* [London School Reprints No. 16, 1933], chaps. 1, 6; for those of perfect monopoly, see R. Triffin, *Monopolistic Competition and General Equilibrium Theory* (Harvard Press, 1940). Perfect monopoly in this sense is merely a technical method of describing a closed economy containing only one economic unit.

norance of the literature and a lack of understanding of scientific methodology.) These limiting concepts obviously cannot be used directly in an empirical study. This is apparent if one asks how our economy differs in detail from one in which entrepreneurs have complete knowledge of future prices and future technological development; no one can know the answer.

The selection of a comparative system which can be used as a frame of reference in judging our present economy will depend almost exclusively upon the purpose of our investigation. The only important purpose of such an investigation is to improve economic policy, so the comparative system should be an alternative form of economic organization which is proposed by the investigator. Historically some form of competitive enterprise economy has been the American choice of method of dealing with the economic problem. It is probably correct to say that this objective was accepted by most of the T.N.E.C. staff and by most of the witnesses, although in both cases the ambiguity of the objective contributed greatly to the wideness of its acceptance.[3] But no attempt was made to define this objective with any precision, and as a result the judgments passed on particular industries (especially in the monographs) are not comparable.

It is necessary, therefore, to replace the standard of a competitive enterprise economy by a more specific comparative system. The system here chosen may be characterized as workable competition, although "workable" is used because it has already gained some currency and not because it is believed that such competition is always practicable. It would take us far afield to defend this choice but it may be observed that, for the chief use made here of the concept, certain other systems (*e.g.*, socialism) would lead to very similar results. The following definition of workable competition is of course tentative; it is designed primarily to illustrate the type of specific criterion which is necessary to a general investigation of monopoly: "An industry is workably competitive when (1) there are a considerable number of firms selling

[3] In its final report, the T.N.E.C. "recommends the maintenance of free, competitive enterprise by the effective suppression of the restrictive practices which have always been recognized as evil." (*Final Report and Recommendations of the T.N.E.C.*, S. Doc. 35, 77th Cong., 1st sess. [Washington, Supt. Docs., 1941], p. 9.)

One example of the ambiguous use of "competition" may be cited:

"The Chairman. Then is it your advice to this committee, as a person of prominence in industry, that the competitive system should be maintained?

"Mr. Greene. I certainly think it should.

"The Chairman. Do you think it would be inadvisable for Congress, by law in any way to weaken the competitive system?

"Mr. Greene. Well, I think the freedom of business from regulation is very important, very desirable." (Hearings, Pt. 18, *Iron and Steel Industry*, p. 10280.)

closely related products in each important market area, (2) these firms are not in collusion, and (3) the long run average cost curve for a new firm is not materially higher than for an established firm."[4] It is probable that in certain cases the definition of perfect competition would have to be approximated more closely. For instance, in the retail market one might also specify that consumers have easy access to information concerning the technical properties of commodities.[5]

Three general problems may be distinguished in an empirical study of the efficiency of an economy, and all were recognized in the course of the T.N.E.C. inquiry. First, there is the question of partial equilibrium analysis: how far do the prices, outputs, investments, employment, quality of product, etc., in various selected industries differ from what they would be if the industries were workably competitive? The measurement of this discrepancy in specific industries would be a difficult task. To know price and output in an industry under workable competition, for instance, it would be necessary to know the demand curve, and the difficulties involved in statistical studies of demand, especially for nonagricultural products, are notorious. But two comments on these difficulties are in order. A reasonable approximation is all that is needed; rigorous mathematical demonstrations are simply in another universe. Moreover, if the economist cannot influence social policy by providing at least approximate quantitative results, he must resort to abstract analysis, for which there is not a wide demand, or to oratory, at which he customarily does not excel.

These comparisons of actual prices and outputs with those which would rule under workable competition would, if carried out for numerous industries, provide one important basis for the formulation of legislative policy and the administration of the antitrust laws. What is more important, they would serve as an intelligible basis for public decisions concerning economic policy. Many economists seem to enjoy emphasizing the fact that "consumers" are indifferent and unorganized (one cynic has called them the great unwashed) but few point out the fact

[4] The first two points serve to eliminate not only monopoly and explicit collusion but also tacit avoidance of price competition for fear of retaliation of close rivals. The necessary number of firms is relevant to such questions as "trust-busting," but it has no bearing on the measure of departure of an industry from workable competition. The third point excludes direct and indirect controls of entry of new firms.

[5] Professor Clair Wilcox's definition, "the availability of buyers of genuine alternatives in policy among their sources of supply" (C. Wilcox, *Competition and Monopoly in American Industry*. T.N.E.C. monog. no. 21 [Washington, Supt. Docs., 1940], p. 8), appears to be too loose; one could always use something else in place of aluminum. Professor J. M. Clark's discussion for the case of the long run harmonizes fairly well with the definition here advanced; see "Toward a Concept of Workable Competition," *Am. Econ. Rev.*, Vol. XXX (June, 1940), pp. 241-49.

that specific information which can be assimilated by the nonprofessional is rarely available in a form which bears a reasonably direct relationship to economic policy.

With respect to this objective, the T.N.E.C. rates a very low score. In only a very few cases is a specific comparison undertaken of the present facts in an industry with those which would rule under workable competition.[6] Customarily not even the most fundamental data (*e.g.*, costs) were provided. This failure is attributable, I believe, to three factors: (1) First and most important, the T.N.E.C. did not have a specific program, it did not define fundamental terms, and it did not erect precise criteria. (2) The constituency of the committee and the nature of the public hearings were ill-suited to detailed and technical discussions of this nature.[7] (3) Some of the research was conducted by agencies which yielded to the temptation to compile data "which will provide an invaluable basis for future work on this subject."

The second major problem is concerned with the much discussed question: How competitive is the economy as a whole? Despite the frequency with which dogmatic answers are given to this question, it is doubtful whether any meaningful answer is attainable. If the comparisons of actual conditions with those ruling under workable competition were carried out for all important industries, the results could scarcely be combined. In one industry the investment would be too large, in another too small; in one industry quality would be inferior, in another price too high. And waiving the difficulty of combining such diverse elements into a single index, there would remain the fact that partial equilibrium studies cannot be added together: the divergences in any one industry depend upon the extent of competition elsewhere. Aside from such weighty objections, it is difficult to find any important purpose in asking how competitive an economy is. There is some intellectual curiosity in knowing how much smaller national income is than it would be under workable competition (where practicable!), but the curiosity does not merit huge expenditures for a crude and unsatisfactory answer.

The third problem, the explanation of unemployment and the level

[6] Professor James estimates the cost to consumers of the duties and quotas on sugar and rayon at 274 million dollars and 70 million dollars per year respectively (*Industrial Concentration and Tariffs*, monog. no. 10, chap. 7). The hearings on the sulphur industry imply that the price of sulphur would be about $7.00 or $8.00 a ton, and not $18 as with the present duopoly (Hearings, Pt. 5, *Monopolistic Practices in Industries*, pp. 1992 *ff.*). There are some relevant data in Professor Warren C. Waite's study of federal milk price fixing programs (*Economic Standards of Government Price Fixing*, monog. no. 32, pp. 87-91); and some of the testimony in the Hearings is also pertinent (Hearings, Pt. 7, *Milk Industry; Poultry Industry*, pp. 2782 *ff.*, 2831 *ff.*).

[7] See the reactions of the committee to the discussion of marginal cost curves (Hearings, Pt. 26, *Iron and Steel Industry*).

of output of the economy, is treated at length in Dr. Abramovitz's able paper. Yet it may be permissible to reëmphasize the fact that the T.N.E.C. almost completely ignored the monopoly question at this point. Only one school of monetary theorists, the depression-minded Keynesians, were heard.[8] The discussion ran primarily in terms of the *technical* exhaustion of private investment opportunities. Virtually no attention was paid to the effects on private investment of cost-price relationships, and more particularly of monopoly—a problem, incidentally, of which price flexibility is only a small part.[9] Considering the auspices under which the studies of unemployment of resources were presented, this neglect seems inexcusable.

II—Competition and Monopoly in the Economy

Three types of information are provided by the T.N.E.C. with respect to the extent of competition and monopoly in the economy. They are (1) a general survey of secondary materials, (2) large scale statistical investigations, and (3) a variety of investigations of particular industries.

In his general survey, Professor Clair Wilcox[10] classifies industries as workably competitive or monopolistic, and then divides this latter class into three groups (monopoly, oligopoly, and cartels), primarily on the basis of the form of market organization. I have already expressed the opinion that the task was well done,[11] but this type of approach is subject to two important limitations. First, as the preceding discussion argues, we do not yet possess the information to classify industries accurately as workably competitive or otherwise, and the

[8] Hearings, Pt. 9, *Savings and Investment.*

[9] The topic of monopoly received little explicit attention—none from Currie or Hansen—and no important additions were made to our theoretical or factual knowledge. On the general question, see *Saving, Investment and National Income,* monog. no. 37, p. 101; *Technology in our Economy,* monog. no. 22, Pt. II, chap. 4; on housing, see Hearings, Pt. 11, *Construction Industry; Toward More Housing,* monog no. 8, Pt. I, chap. 5; on natural gas, see *Reports of the Federal Trade Commission,* monog. no. 36, pp. 71 *ff.* Martin Taitel attempted to prove by means of a statistical study that the importance of the profit rate in investment decisions has been exaggerated. "Factors other than the amount or the rate of profit have been the major determinants of the level of capital expenditures of groups of companies. Of these other factors, the most important have been the level of output in relation to capacity and the pressure upon business for the introduction of available new technologies." (*Profits, Productive Activities and New Investment,* monog. no. 12, p. xix.) But surely technological improvements and the rate of operation are really only two of the factors affecting the profit rate, and both influence investment decisions through the profit rate. Dr. Abramovitz has pointed out that a convincing statistical demonstration of the unimportance of the profit rate would require (1) use of expected, not realized, profits, and (2) comparison between industries in which entry is easy.

[10] *Competition and Monopoly,* monog. no. 21.

[11] See my comments, this *Review,* Vol. XXXI (September, 1941), pp. 573-74.

T.N.E.C. did little to remedy this defect. Second, and more important, we do not know how far the monopolistic industries depart from workable competition. If the list of monopolistic industries expands, it is not possible to state with any assurance that the economy is less competitive.

It is worth emphasizing that a general survey in nonquantitative terms, such as Wilcox's (or Burns's), is almost certain to leave an exaggerated impression of the extent of monopolization of the economy. The competitive industries are essentially similar in their characteristics and broad patterns of behavior, so they receive brief attention in order to avoid tiresome repetition. The monopolistic industries are much more varied in their market practices, and they provide an unlimited number of examples of chicanery, exploitation, and other savory literary items. As a result the distribution of space and emphasis is always biased. Wilcox, for instance, devotes approximately equal space to the huge, competitive women's apparel industry and to beryllium, yet the sales of the latter commodity are probably less than those of any one size of cotton dress.

In *The Structure of Industry*[12] several broad statistical studies of concentration are presented. The first is a study of employment and product per establishment (plant) in manufacturing industries; the averages rose 35 and 80 per cent respectively from 1914 to 1937.[13] These averages are not sufficiently relevant to the question of the extent of competition to merit analysis here. Somewhat more pointed measures of concentration are also computed for 195 industries, on the basis of the number and proportion of plants employing half of the workers in each industry.[14] There are several difficulties in interpreting the results of this study. The data as presented do not tell us the extent of concentration in individual industries, but only changes relative to 1914. The tests of concentration are relatively crude.[15] And the Presi-

[12] Monog. no. 27.

[13] *Ibid.*, p. 4.

[14] In a given industry, let there be n plants in the base year (1914) employing $x_1, x_2, \ldots, x_n$ workers in decreasing order of size; the first p plants employ half of the workers. In any given year, let there be m plants employing $y_1, y_2, \ldots, y_n$ workers in decreasing order of size; the first q plants employ half of the workers (*ibid.*, pp. 54 *f.*). Then the absolute index (AI) is defined as

$$AI = p/q \times 100.$$

The relative index (RI) is defined as

$$RI = \frac{p}{n} / \frac{q}{m} \times 100.$$

Hence AI = n/m RI.

[15] The following example will suffice. Let employment be the same in 1914 and 1917 in a given industry. If in 1914, 15 equal-sized plants hire half the labor and 100 plants hire the remainder, and in 1917 one plant hires 30 per cent of the labor, the next 19 plants 20 per

dent's request, to study "the effect of concentration on the decline of competition," is unfortunately ignored here as elsewhere in the monograph.

The other statistical survey measures the concentration ratios (ratio of the output of the four largest firms to United States production) for 1807 products of manufacturing industries. There is one grave defect in the statistical procedure: the *production* of domestic concerns is the basis of the computation. Surely the domestic consumption *plus* imports should have been used if the findings are to be interpreted as evidence of the extent of monopoly in the domestic economy. This oversight introduces a fairly systematic bias in the direction of exaggerating concentration.[16] Moreover, this bias is very large, as the following tentative corrections show:[17]

	Concentration Ratio	
Commodities	*Monograph No. 27*	*Revised to Include Imports*
Newsprint	68.1	15.2
Crude Glycerine	40.2	24.8
Acetic Acid	73.4	58.4
Sodium Sulphate	63.0	35.2
Tin	89.6	.4
Cigarette Paper	71.6	50.4
Burlap	39.6	23.4
Rayon Waste	70.9	32.6
Whiskey	40.0	25.1

The omission of imports is therefore sufficient, I believe, to vitiate the conclusions of the monograph.[18]

Even if concentration ratios are revised, however, they are a poor index of monopoly. They minimize the extent of monopoly control in many cases: all markets are treated as national; collusion between firms is not considered; and physically similar commodities are treated as identical. But, on the other hand, intercommodity competition is ignored, and this is an equally fatal defect. For instance, over 5 per cent of the products are in the textile group, and almost all of these have

cent, and 95 plants the remainder, the absolute index is 75 and the relative index is also 75. Yet monopoly power has very probably increased.

[16] This is obvious when the commodity is on an import basis. If the commodity is exported, on the other hand, the concentration ratio used in the monograph does not systematically understate concentration, for all companies usually are or can be in both domestic and export markets. The concentration ratio will be increased if one of the four largest firms is also a large importer (*e.g.*, copper) and it may be increased when an importer is one of the four largest "producers."

[17] The data are taken from *Structure of Industry*, monog. no. 27, pp. 420 *ff.*, and from the *Statistical Abstract;* the year is 1937. The corrections are probably exaggerated in some cases because it is not known who the importers were.

[18] The same criticism can be made of the concentration ratios in the National Resources Committee's *The Structure of the American Economy.*

nigh concentration ratios. Yet the substitution possibilities on the supply side (to say nothing of the demand side) between many of these similar products make it reasonably certain that monopolistic powers are in general small.[19] Again, the concentration ratio for motor vehicles is almost 90, but this ratio takes no cognizance of the large used-car market. It is doubtful whether the monopoly question will ever receive much illumination from large scale statistical investigations.

In addition to these broader studies, numerous monographs and most of the Hearings are devoted to specific industries and groups of industries.[20] These individual studies range in quality from the very good to the very bad, but it would be unfair to itemize the groups without a detailed justification which is beyond the limits of this paper.

III—The Economies of Large-Scale Production

Let us turn now to some of the bases of monopoly. The bases of monopoly here refer to the conditions or institutions which maintain the monopolistic situation, and not the (fairly obvious) incentives which lead to its formation. Bases for monopoly operate through either limitation of the number of firms or restriction on the market freedom of firms. The first basis to be considered is the economy of large-scale production. The incompatibility of competition and continuing economies of scale is well known;[21] here the existence of economies will be examined.

On general theoretical grounds, only two things can be said about the shape of the long-run average cost curve. First, large outputs have larger total costs than smaller outputs, so the elasticity of the average cost curve is numerically greater than one.[22] Second, long-run average

[19] For example, 16 companies make two-piece men's suits with extra knickers and the concentration ratio is 76.3, but 634 companies make men's three-piece suits (*Structure of Industry,* monog. no. 27, p. 425).

[20] On the group of agricultural industries, see monog. no. 35 (*Large-Scale Organization in the Food Industries*) and my comments, this *Review,* Vol. XXXI (September, 1941), pp. 576-77; and monog. no. 23 (*Agriculture and the National Economy*), which will be commented on below.

[21] A proof may be given. Under competition $p = k$, a constant. Long-run average costs may be denoted $\varphi(x)$, where x is output. Then total profits are

$$\pi = x(k - \varphi)$$

and for maximum profits

$$\frac{d\pi}{dx} = (k - \varphi) - x\varphi' = 0.$$

But $(k - \varphi)$ is positive and $-x\varphi'$ is also positive if there are continuing economies of scale, so the equation has no real roots; the determination of output is complex.

[22] This is sometimes proved formally: if $x_1 > x_0$ and the total cost of x_1 is less than that of x_0, one will produce x_1 even if x_0 is all that is desired and throw the remainder away. I prefer the more empirical (if less rigorous) argument that additional output must require more of some productive services and, within small variations of output, less of none.

cost must (at certain selected outputs) fall at a decreasing rate; the average cost curve is convex to the output axis.[23] Beyond this we cannot go without recourse to the facts. The T.N.E.C. provides facts of several varieties.

The first evidence is a summary by the Federal Trade Commission of the findings in 233 studies of average costs and rates of return on investment in various industries.[24] Using the cost figures, as more directly pertinent to the question of economies, in only one case of 59 did the largest or a large company have the lowest average costs and in only six cases out of 53 did the largest plant have the lowest average costs.[25] These findings are impressive, but they are subject to several important qualifications.

First, this mode of summary in terms of what size firm or plant has lowest costs or highest returns utilizes directly only one observation in each cost study. Such a summary is by no means uninformative, for if a small firm can have the lowest costs in an industry it suggests that economies of scale probably are not of great quantitative importance. But it is unsatisfactory to stop here, for there may still be large correlations between size and efficiency (as measured by average costs); the individual firm may be atypical. This is, in fact, the case in certain of the tests. As examples, the rank correlation between size of plant and efficiency for beet sugar producers is .75[26] and in milk distribution it is .58.[27] Unfortunately this type of analysis cannot be utilized in many cases because of the way in which the data are presented, but it appears that the major conclusions of the monograph would be weakened by this qualification.

Second, the cost and rate of return figures are of course suspect since they are based upon corporate accounts. The Federal Trade Commis-

[23] Although the basic phenomena are well known, they are usually not presented in this form, so a proof may be given. The economies of scale are due to indivisibilities of productive factors and processes. This is a tautology since an indivisible factor is defined as one which does not have the same long-run average cost for all sizes of factor (measured in terms of output). There are two possibilities:

1. In the trivial case where all indivisible factors are most efficiently used at the same output (*i.e.*, have the same "capacities"), average cost is equal at all multiples of this output, —there are no economies of scale as a general trend.

2. If the most efficient outputs ("capacities") vary, average cost will fall at a decreasing rate at multiples of the capacity of the smallest factor. This is true because the lowest (and then the next lowest, etc.) capacity factor will no longer contribute economies of scale. Lowest long-run average cost is of course reached when output is the lowest common multiple of all capacities.

[24] *Relative Efficiency of Large, Medium-Sized, and Small Business,* monog. no. 13.

[25] In the rate of return test the large companies made a somewhat better showing; for a tabular recapitulation see this *Review,* Vol. XXXI (September, 1941), p. 578.

[26] *Relative Efficiency,* monog. no. 13, p. 45.

[27] *Ibid.,* p. 56.

sion assures us that government accountants have reduced the figures to comparability.[28] Examination of some of the detailed reports suggests that the chief corrections are a uniform classification of costs and the elimination of intangibles from investment (and from operating charges?).[29] This is scarcely enough to guarantee comparability. Indeed the theoretical difficulties in rendering costs and investments comparable are so great that the most careful results will be only approximate. Witness the sad tale of utility valuations.

Third, the individual studies are not explored in sufficient detail to insure that the data are trustworthy clues to the shape of long-run average cost curves. The effect of the ratio of output to "capacity" is dismissed too easily.[30] Quality differences in products are not considered, and the dependence of the definition of the size of plant on the size of market area is also passed over. The quantitative differences in costs are not examined, and this is a basic defect. It does not matter much *for any purpose* what size plant or firm is most efficient if the differences are small. A few sample computations lead to the tentative conclusion that, on balance, the costs of large and small companies are fairly close and those of medium-sized plants considerably lower than either.[31]

Finally, for purposes of social policy a distinction should be drawn between technological economies and pecuniary economies. If the larger firm attains lower costs chiefly by use of its bargaining power in buying productive services and factors, the economies represent

[28] *Ibid.*, pp. 5, 11.

[29] See, as examples, *Petroleum Industry: Prices, Profits and Competition* (70th Cong., 1st sess., S. Doc. 61, 1928), pp. 266-70; *Competition and Profits in Bread and Flour* (70th Cong., 1st sess., S. Doc. 98, 1929), p. 27, chap. viii, especially p. 279. In this latter report it is shown that profits of small and closely held companies are partially included in executives' salaries, and this practice tends to exaggerate the costs of small firms (*ibid.*, pp. 309-10).

[30] It is said that some adjustments have been made (when, how?), and that this factor can be "overrated" (*Relative Efficiency*, monog. no. 13, p. 19). The figures for cement—the illustration used by the F.T.C.—show a rank correlation between operating ratios and efficiency of .47 (*ibid.*, p. 24).

[31] The following are examples taken from the monograph (the page references follow the name of the commodity or industry): P represents plants, C, companies:

Commodities	*Large*	*Medium*	*Small*	*Very Small*
P: Pig iron (p. 26)	$13.28	$12.86	$13.21	$14.03
C: Petroleum (p. 38)	1.19	.84	1.12	1.48
C: Beet sugar (p. 45)	3.57	3.86	4.47	——
C: Milk distribution (p. 56)	3.29	2.60	3.58	——
C: Evaporated milk (p. 59)	5.02	4.75	5.14	——
P: Flour (p. 60)	1.09	1.11	1.03	1.12
C: Flour (p. 65)	6.15	5.80	5.95	——

If a few of the small firms with very high costs were eliminated, the differences would be considerably smaller. Thus the five highest cost producers of beet sugar raise the average of small companies from $4.19 to $4.47.

dent's request, to study "the effect of concentration on the decline of competition," is unfortunately ignored here as elsewhere in the monograph.

The other statistical survey measures the concentration ratios (ratio of the output of the four largest firms to United States production) for 1807 products of manufacturing industries. There is one grave defect in the statistical procedure: the *production* of domestic concerns is the basis of the computation. Surely the domestic consumption *plus* imports should have been used if the findings are to be interpreted as evidence of the extent of monopoly in the domestic economy. This oversight introduces a fairly systematic bias in the direction of exaggerating concentration.[16] Moreover, this bias is very large, as the following tentative corrections show:[17]

	Concentration Ratio	
Commodities	*Monograph No. 27*	*Revised to Include Imports*
Newsprint	68.1	15.2
Crude Glycerine	40.2	24.8
Acetic Acid	73.4	58.4
Sodium Sulphate	63.0	35.2
Tin	89.6	.4
Cigarette Paper	71.6	50.4
Burlap	39.6	23.4
Rayon Waste	70.9	32.6
Whiskey	40.0	25.1

The omission of imports is therefore sufficient, I believe, to vitiate the conclusions of the monograph.[18]

Even if concentration ratios are revised, however, they are a poor index of monopoly. They minimize the extent of monopoly control in many cases: all markets are treated as national; collusion between firms is not considered; and physically similar commodities are treated as identical. A few sample computations lead to the tentative conclusion that, on balance, the costs of large and small companies are fairly close and those of medium-sized plants considerably lower than either.[31]

Finally, for purposes of social policy a distinction should be drawn between technological economies and pecuniary economies. If the larger firm attains lower costs chiefly by use of its bargaining power in buying productive services and factors, the economies represent

[28] *Ibid.*, pp. 5, 11.

[29] See, as examples, *Petroleum Industry: Prices, Profits and Competition* (70th Cong., 1st sess., S. Doc. 61, 1928), pp. 266-70; *Competition and Profits in Bread and Flour* (70th Cong., 1st sess., S. Doc. 98, 1929), p. 27, chap. viii, especially p. 279. In this latter report it is shown that profits of small and closely held companies are partially included in executives' salaries, and this practice tends to exaggerate the costs of small firms (*ibid.*, pp. 309-10).

[30] It is said that some adjustments have been made (when, how?), and that this factor can be "overrated" (*Relative Efficiency*, monog. no. 13, p. 19). The figures for cement—the illustration used by the F.T.C.—show a rank correlation between operating ratios and efficiency of .47 (*ibid.*, p. 24).

[31] The following are examples taken from the monograph (the page references follow the name of the commodity or industry): P represents plants, C, companies:

Commodities	*Large*	*Medium*	*Small*	*Very Small*
P: Pig iron (p. 26)	$13.28	$12.86	$13.21	$14.03
C: Petroleum (p. 38)	1.19	.84	1.12	1.48
C: Beet sugar (p. 45)	3.57	3.86	4.47	——
C: Milk distribution (p. 56)	3.29	2.60	3.58	——
C: Evaporated milk (p. 59)	5.02	4.75	5.14	——
P: Flour (p. 60)	1.09	1.11	1.03	1.12
C: Flour (p. 65)	6.15	5.80	5.95	——

If a few of the small firms with very high costs were eliminated, the differences would be considerably smaller. Thus the five highest cost producers of beet sugar raise the average of small companies from $4.19 to $4.47.

transfers and not net social gains. It is not possible to separate these two types of economies in the F.T.C. data, or for that matter in the other cost studies here considered.[32]

A second measure of economies of scale rests on the following hypothesis: that the amount of electrical energy per man-hour in plants of various sizes is a good index of the adoption of "more modern and efficient types of technological equipment" and hence of the relative efficiencies of the various sizes of plants.[33] In each of 21 industries surveyed, the electrical energy per man-hour increased with the size of plant. The loosely formulated hypothesis scarcely carries conviction. The labor used in larger plants is probably more efficient,[34] and the products of these industries are doubtless also very heterogeneous. Nor does lower labor cost (if it is lower) per unit of output necessarily imply lower average costs for large plants.[35] The investigation may be only an illustration of the law of variable proportions.

The statistical analysis of the costs of the U. S. Steel Corporation made by Professor Yntema is the chief new material on the subject of costs in the T.N.E.C. record.[36] The cost curves derived are of a short-run nature,[37] but they cast light on the probable shape of the long-run average cost curve. The chief finding, it will be recalled, is that the total cost function of the U. S. Steel Corporation (as of 1938) was $C = \$182{,}000{,}000 + \$55.73\ Q$, where C is total cost and Q is tons of output.[38] Hence marginal costs are constant (and equal to $55.73) over an observed range from 4 to 15 million tons of output.

This finding of constancy of short-run marginal costs, which has also emerged from other costs studies, is open to a considerable number of objections which need not be examined here.[39] If we take the findings

[32] Difference in price paid for materials, for example, is due in part to the economies accruing from larger orders and shipments. Even the price-conscious steel industry, however, grants to large buyers concessions which are too large to be explained on cost grounds (Hearings, Pt. 20, *Iron and Steel Industry,* pp. 10788 *ff.*).

[33] *Technology in Our Economy,* monog. no. 22, p. 203.

[34] Large companies (and plants?) in general pay higher wages (*Hourly Earnings of Employees in Large and Small Enterprises,* monog. no. 14), and this differential is probably due in large part to the fact that large companies have more selective personnel policies.

[35] This point is also relevant to the studies of the effect of scale of operations on man-hours of labor per unit of output (*Technology in Our Economy,* monog. no. 22, pp. 200-02). The data on short-run labor inputs (*ibid.,* p. 97) are not relevant to the question of economies of scale; the validity and interpretation of these data are open to some question.

[36] Hearings, Pt. 26, *Iron and Steel Industry.*

[37] More accurately, they are a peculiar variant of the Marshallian short-run curves, for the effects of technological improvements and plant expansions are "removed" only to the extent that they manifest themselves in (linear) trends in the time series used.

[38] Hearings, Pt. 26, *Iron and Steel Industry,* p. 14034.

[39] See the testimony of Professor de Chazeau and Mr. Taitel (*ibid.,* pp. 13617 *ff.,* 13694 *ff.*); R. Ruggles, "The Concept of Linear Total Cost-Output Regressions," this

at their face value, two possible explanations seem possible. First, variations in output are effected by approximately equal changes in the employment of all factors; the coefficients of production are fixed. Second, the increase in the efficiency of utilization of fixed factors as output increases is approximately offset by decreasing efficiency of labor and other variable factors, an improbable situation.[40] If the first explanation is correct, as it undoubtedly is in many cases, then there should be few economies of scale, for expansion of plant will occur by way of adding more machines, not using larger ones.[41] These cost studies by implication support the conclusion of the F.T.C. study.

In the petroleum hearings, one witness submitted an estimate of operating costs for three sizes of modern gasoline refineries.[42] The salient figures are as follows:

Item	*Size of Refinery (barrels per day)* 5,000	15,000	60,000
Capital Investment	$2,000,000	$5,000,000	$16,000,000
Direct Operating Expense	.16	.11	.08
Total Cost of Processing a Barrel of Crude Oil	.337	.259	.201

The details of the cost analysis are unfortunately omitted,[43] so it is difficult to assess the significance of these data. Nevertheless the general method of securing costs for hypothetical plants of various sizes has several advantages over the customary statistical studies, and it is to be hoped that more such studies—with details—will become available.

The remainder of the T.N.E.C. material on costs may be passed over quickly. There are comments on the optimum size of plant in numerous industries,[44] but such observations are not very useful. The detailed evidence for the figures is not presented, and quantitative differences in

Review, Vol. XXXI (June, 1941), pp. 332-35; and my comments, this *Review*, Vol. XXX (March, 1940), pp. 401-02.

[40] If there is much specialized plant, the short-run marginal cost curve will be steep. If flexibility is built into the plant, the question turns on how the flexibility is attained. If it is secured by (*e.g.*) using numerous small machines rather than a few large ones, we are thrown back to the first explanation. See my "Production and Distribution in the Short Run," *Jour. of Pol. Economy*, Vol. XLVII (June, 1939), pp. 305-27.

[41] If the short-run marginal cost curve rises, no conclusion can be drawn respecting the shape of the long-run average cost curve.

[42] Hearings, Pt. 15, *Petroleum Industry*, pp. 8636 *ff.*, 8661 *ff.*

[43] For instance, the largest plant contains two "good-sized" combination skimming and cracking units (*ibid.*, p. 8351); in fact, each of these units "is about as large as we know how to build" (*ibid.*, p. 8352). Why are two units necessary?

[44] *E.g.*, a modern, semi-integrated steel plant costs $100,000,000 (*Technology in Our Economy*, monog. no. 22, p. 199), or anyway $40,000,000 (Hearings, Pt. 18, *Iron and Steel Industry*, p. 10410); a company producing 100,000 automobiles a year has no serious handicaps (Hearings, Pt. 21, *War and Prices*, pp. 11216 *ff.*); a distillery with a capacity of 1300 gallons a day is apparently efficient, especially on a farm (Hearings, Pt. 6, *Liquor Industry*, pp. 2543 *ff.*); etc.

costs of plants of different sizes are not considered although this is really the crucial question.

As with so many topics, therefore, the reader will find it easy to leave the T.N.E.C. publications with much the same ideas with which he approached them. With respect to economies of scale the writer has so fared: he retains the view that beyond a relatively modest scale of output the economies of large scale production are in general quantitatively unimportant.

IV—The Rôle of Government

The efforts of governments to repress competition may now be considered. The federally-financed T.N.E.C. spent considerable time on the familiar state and local restrictions on competition,[45] but passed rather quickly over the much more important part which has been and is being played by the federal government. In this essay, financed on a somewhat more modest scale by a state institution, the distribution of emphasis will be reversed and the meager contributions to the subject of federal intervention will be summarized. Seven cases will be considered.

1. *Foreign trade, tariffs.* Professor Cyril James instituted an investigation of the effects of tariffs on domestic competition.[46] The fundamental finding is that of 317 products whose concentration ratios (taken from monog. no. 27) exceed 75 per cent, 27.7 per cent by value would have lower prices if tariffs were reduced because "monopolistic elements" in domestic prices would be offset.[47] Unfortunately the critical information on which his results turn is not included in the monograph, so the validity of the findings cannot be assessed. It is also regrettable that products with low concentration ratios (*e.g.*, dairy products) were not included, for combinations of producers have also secured much assistance from the federal government.[48]

[45] In addition to state trade barriers (Hearings, Pt. 29. *Interstate Trade Barriers*), there is material on building codes (Hearings, Pt. 11, *Construction Industry*, pp. 5317 *ff.*), price-maintenance laws (*Problems of Small Business*, monog. no. 17, chap. 16; *Price Behavior and Business Policy*, monog. no. 1, Pt. 3; *Final Report*, pp. 141 *ff.*); milk markets (*Economic Standards of Government Price Control*, monog. no. 32, Pt. 2, chaps. 2-6); and oil conservation (*Control of the Petroleum Industry by Major Oil Companies*, monog. no. 39, chap. 3).

[46] *Industrial Concentration and Tariffs*, monog. no. 10.

[47] In a study of export policies of 76 companies, Milton Gilbert observed: "In many cases, however, approximately half in our sample, the protective tariff is of prime importance in the maintenance of a high degree of monopolistic competition or a monopoly position" (*Export Prices and Export Cartels*, monog. no. 6, p. 82).

[48] Some aspects of sugar and lumber are studied (*Industrial Concentration and Tariffs*, monog. no. 10, chaps. 6, 7).

The unsatisfactory report made by the F.T.C. on the Webb-Pomerene associations does not even allude to the possible tendency of these associations to restrict domestic competition.[49] This omission cannot be attributed to the lack of evidence of such a tendency.[50]

2. *Patents*. The subject of patents received a good deal of attention from the T.N.E.C., and it was the only case, so far as I know, in which at least minor legislative reforms have resulted from the work of the committee,[51] which also recommended a twenty-year limitation on patents from date of application, compulsory licensing, prohibition of restrictive licensing, and certain technical changes in administration.[52] In addition there were numerous suggestions from individuals, one of the most intriguing of which was Professor Walton Hamilton's proposal that patents of decreasing term be given for discoveries characterized by genius, professional competence, and mechanical ability.[53]

Disregarding matters of technical procedure and administration, on which I do not possess the mechanical ability to pass, two basic problems were posed: (1) the use of patents to evade the antitrust laws; and (2) the proper reward to be given to inventors. With respect to the first problem, the cartellization of the glass-container industry by the Hartford Empire Company was an eloquent example of an evil demanding correction,[54] and Professor Hamilton's useful survey of judicial decisions on this matter emphasizes the fact that the remedy must be legislative.[55] The case for limitation of restrictive licensing is surely irrefutable.

But the question of the proper reward to be given to inventors was not approached in useful terms. Almost every witness expressed his opinion as to whether patents were or were not necessary to stimulate invention, but these opinions would be of little value even if they had been uniform. (One witness seems to have summarized the prevailing attitude: "That 17 years seems to have worked out very well for a hundred years. Why change it?"[56]) The relevant question is a quantitative one: Will the social gains from a reduced patent term exceed the loss from discouragement of invention? The social gains flow from reduced monopoly: earlier use, lower prices, greater investment, etc.

[49] *Export Prices and Export Cartels (Webb-Pomerene Associations)*, monog. no. 6, Pt. 3.

[51] *Patents and Free Enterprise*, monog. no. 31, p. 146n.

[52] *Final Report*, pp. 36-37; also pp. 249-51. None of the basic proposals has been adopted.

[53] *Patents and Free Enterprises*, monog. no. 31, pp. 156-57.

[54] Hearings, Pt. 2, *Patents*.

[55] *Patents and Free Enterprise*, monog. no. 31.

[56] Hearings, Pt. 2, *Patents*, p. 322.

That a shorter term would lessen the researcher's incentive is probable (although not certain),[57] although one should keep in mind both the distinction between inventor and patentee and the possible alternative methods of stimulating technological progress.

A large part of the answer to this question, surely, would be provided by an examination of the amount of return on a selection of patents five, ten, fifteen and twenty years after the date of application, and some estimate of the gains from an earlier lapse of the patent. Similarly, the practicability of compulsory licensing might be examined through its hypothetical application to numerous patents and by consideration of detailed foreign experience with this technique.[58] As the situation now exists, each person has his own opinion, arrived at intuitively, as to the proper patent term, the feasibility of compulsory licensing, the net effects of patent pools, and similar problems. One of the most plausible of these judgments, that a seven- to ten-year patent term better combines equitable treatment of inventors, protection of society, and administrative simplicity, receives no consideration.

3. N.R.A. Even if the Blue Eagle had left no progeny, it would still be useful to view in retrospect the workings of government by trade association. Professor Clair Wilcox's concise summary of cartel-features of the codes is therefore very welcome.[59] But, of course, the progeny have been most numerous. In some cases (coal, trucking), special legislation has restored monopolistic arrangements. The more important effects, however, were to strengthen greatly the trade association movement, which had suffered reverses from 1930 to 1932,[60] and to increase the price-fixing activities of these and less formally organized groups of producers.[61] There is fragmentary evidence on the persistence of

[57] On the ground that additional rewards will not directly discourage anyone and will encourage some avaricious inventors. But the reduction of patent monopolies would lead to wider production of the patented object, and improvements or derivative ideas might emerge more rapidly.

[58] Since Mr. Coe was available, such studies should have been simple: "Mr. Coe. In the last 5 years of my service as Commissioner of Patents I have devoted myself to a careful study of almost every aspect of our patent system. This I have done not merely for my own information but with the purpose of increasing the usefulness of the system to the American people. In the course of this long and serious study I have utilized every available source of information." (Hearings, Pt. 3, *Patents*, p. 838). There is an illuminating dispute between Messrs. Coe and Arnold in Hearings, Pt. 31A, *Supplemental Data*, pp. 18467-89.

[59] See *Competition and Monopoly*, monog. no. 21, pp. 259-67; Hearings, Pt. 25, *Cartels*, pp. 13319 *ff.*; and *Final Report of the Executive Secretary*, pp. 98-101.

[60] *Trade Association Survey*, monog. no. 18, pp. 12 *ff.*, 369.

[61] In this connection it may be of interest to quote the testimony of Thurman Arnold: "May I interject this in the record with respect to the Department of Commerce report [*Trade Association Survey*, monog. no. 18], which says that trade associations are not violating the law? I don't believe that it is possible for anybody to know whether any association is violating the law or not without a grand-jury investigation. I would only say that the majority of trade associations against whom we have had substantial complaints

N.R.A. coöperation—for example, the iron ore company executives had apparently not yet heard in 1938 of the *Schechter* decision[62]—but no systematic study was made.

4. Agriculture. Of federally fostered monopolies, agriculture is surely one of the most important. The broad subject is discussed only by Dr. A. L. Meyers, and this discussion is brief and nonfactual.[63] The government program is held to be nonmonopolistic because maximum returns are not sought and because social considerations (favoring small farms, aid to sharecroppers) are given attention.[64] Surely both arguments are equally valid (or invalid) when applied to antichain store legislation, which is accorded less favorable treatment.[65] Later Dr. Meyers shifts ground and concedes that competitively-oriented criticisms of the agricultural programs are "theoretically sound," but falls back on the familiar argument that farmers must organize to combat industrial monopolies in order to receive (120 per cent of?) parity incomes.[66]

The development of federal price fixing in milk is reported in an informative, balanced essay by Professor W. C. Waite.[67] The early marketing agreements in interstate markets were dominated, and in large part administered, by local organizations of producers and distributors. Under the subsequent licensing scheme the distributors were left to care for themselves, and the interests of the producers—and, to an apparently infinitesimal extent, of consumers—became the concern of the Department of Agriculture. Certain improvements have been made in the marketing machinery,[68] but the major results have been an increase in milk prices (of 20 to 40 cents per hundredweight) and a strengthening of the powers of producer organizations, which, incidentally, possess veto powers over the Department of Agriculture's marketing orders.

5. Bituminous coal. The compulsory cartellization of the coal industry is an extremely important case of governmental intervention because of both the basic importance of the industry (which employs over half

---

have been found to have been violating the law, and we have collected a large number of fines against them. As to the complaints which we haven't investigated, I don't think either the Department of Commerce knows, or we know, or anybody knows" (*Final Report,* p. 305).

[68] *Ibid.,* pp. 74, 92.

a million laborers) and its probable use as a precedent. On the one hand, minimum prices are established primarily to protect union wage rates, and on the other hand, marketing associations are exempted from the antitrust laws. Unfortunately the only T.N.E.C. study of coal is restricted primarily to technical problems of price determination under the unusually cumbersome procedures dictated by the Bituminous Coal act of 1937.[69] This study dismisses competition—in considerable part because it is not "orderly" (rigid?)—in a page,[70] and indeed the authors recommend strengthening the cartel features by introduction of production controls, compulsory marketing associations, and regulation of substitute fuels.[71] For a critical appraisal of the workings of the Bituminous Coal act, other sources must be consulted.[72]

6. Labor Unions. The delicate topic of labor organizations, it need scarcely be said, was not submitted to close scrutiny by the T.N.E.C. In this respect it is interesting to note that the Industrial Commission, working at a time (1901) when the question was somewhat less important, devoted more attention to labor than did the T.N.E.C. Hearings.[73] It is surely indisputable that New Deal encouragement has been the greatest factor in the recent ascendancy of labor unions, so it is most appropriate to discuss the effects of union policies on competition at this point. The problem can be subdivided as follows: (1) the effects of labor unions on competition among employers; (2) policies of unions in the labor markets; and (3) the direct prevention of competition by the federal government.

Information concerning the effects of unions on competition among employers is virtually nonexistent. Thurman Arnold cites a case or two where unions have suppressed small concerns to "stabilize" an industry.[74] There is also evidence of efforts of drivers' unions to prevent competition in milk marketing,[75] of the important part played by

[69] E. B. Gordon and W. Y. Webb, *Price Fixing in the Bituminous Coal Industry,* monog. no. 32, Pt. III. But consult also the sections in Professor Donald Wallace's summary (*ibid.,* Pt. IV, chaps. 6, 8, 11).

[70] *Ibid.,* p. 320.

[71] *Ibid.,* p. 328.

[72] See the excellent essay by E. V. Rostow, "Bituminous Coal and the Public Interest," *Yale Law Jour.,* Vol. 50 (February, 1941), pp. 543-94.

[73] For a summary, see M. Atkinson, "Trusts and Trade Unions," *Pol. Sci. Quart.,* Vol. XIX (1904), pp. 193-223.

[74] For evidence on the first two points of our subdivision, see his memorandum, *Final Report,* pp. 164 *ff.*; also Corwin Edwards, "Public Policy toward Restraints of Trade by Labor Unions; and Economic Appraisal," *Am. Econ. Rev.,* Suppl., Vol. XXXII (March 1942), pp. 432-48. The reactions of the American Federation of Labor and a railroad brotherhood of Arnold's statement were obvious but depressing; Corwin Edward's commentary is excellent (Hearings, Pt. 31A, *Supplemental Data,* pp. 18168-94).

[75] Hearings, Pt. 7, *Milk Industry, Poultry Industry,* pp. 2944 *ff.,* 3223 *f.*

unions in the New York poultry racket,[76] and of the enforcement of monopolistic agreements in the building industry.[77]

The marketing policies of labor unions also receive practically no consideration. Trifling attention is paid to rackets—the Chicago (!) witness who used this word was reprimanded by members of the T.N.E.C.[78] But what is more important, the effects of wage rates, hours, and output policies of unions on prices, investments, and employment were not explored. The one monograph dealing with this subject is concerned only with the situation in individual firms, and questions of general effects or policies are not raised.[79] In the study of bituminous coal pricing the problem is dismissed as follows: "Fears have been expressed that the public has no protection, under such a plan [of legally enforceable minimum prices], against excessive wage scales which under favorable conditions might conceivably [*sic!*] be forced through perfectly legal negotiations. These authors can hardly picture labor forcing unreasonable wage levels upon an industry whose prices would shoot upward, when as a result the industry upon which they depend for their livelihood would be faced by probable losses of tonnage and employment because more consumers would be driven to lower-priced competing fuels."[80] Aside from the observable falsity of this attitude, it might be useful to mention that the "reasonableness" of a wage structure should be judged in terms of economic effects as well as in terms of the niceness of everyone receiving good incomes.

The final point, positive intervention in labor markets by the government, is completely omitted. There is no reference of importance to the Fair Labor Standards act or to the Walsh-Healey act.

7. War. Although the T.N.E.C. lasted more than fifteen months after the outbreak of the European war and held a set of hearings on *War and Prices*,[81] the effects of war on competition were not considered. Nevertheless, the current interest in the topic is sufficient to justify a few comments. It is certain that competition diminishes sharply during a major war, and it is probable that competition does not regain its former position after the demobilization. The following are a few bases for this generalization.

First, those in charge of procurement, rationing, and price fixing find it much easier to deal with associations of producers than individually with numerous small producers, so organizations of producers are

[76] *Ibid.*, pp. 2869 *ff.*

[77] Hearings, Pt. 11, *Construction Industry*, pp. 5007 *ff.*; *Toward More Housing*, monog. no. 8, pp. 54 *f.*, 134.

[78] Hearings, Pt. 11, *Construction Industry*, pp. 5247 *ff.*

[79] *Industrial Wage Rates, Labor Costs and Price Policies*, monog. no. 5.

[80] *Economic Standards of Government Price Control*, monog. no. 32, p. 327.

[81] Hearings, Pt. 21, *War and Prices.*

fostered. During World War I the number of trade associations increased greatly.[82] There is likely to be virtual suspension of antitrust laws in the ubiquitous defense industries.[83]

Second, small concerns are less likely to secure war orders because of inadequate information of government needs, aversion of procurement officials to dealing with small orders, and resistance of large companies (for a variety of reasons) to subcontracting. Moreover, in the great flood of administrative decisions (*e.g.*, the granting of 75,000 priority ratings a month) the small concern, lacking a skilled representative or "influence," will not always fare so well. The situation is pithily described before the Truman Committee Hearings by Senator Connally: "You say anything to the Army and Navy about powder and the first thing they say is 'du Pont. We will get du Pont to do that.' "[84]

Third, the production of civilian goods may be concentrated in a few plants for a variety of reasons, not all of which are convincing. The British have already employed this method extensively, especially in the textile industry,[85] and certain characteristics of the scheme have already been introduced in the United States.[86]

[82] *Trade Association Survey,* monog. no. 18, p. 369.

[83] The signs already point in this direction. For example, the antitrust suit against the leading oil companies which was announced July 27, 1940, was immediately referred to the National Defense Advisory Commission, apparently at the latter's request. The commission reported unfavorably on the most important part of the government's suit, the attempt to divorce ownership of transportation facilities. The reason given by the commission, and (perforce) accepted by Attorney General Jackson, was that outside capital was unwilling to take over the pipe lines (which earned only 10 to 30 per cent on investment, depending upon the investment figures used). At the time it was also argued by many that new pipe lines construction, later prohibited by S.P.A.B., would be discouraged. (See *New York Times,* July 27, August 1, September 29, 1940.) Since the above was written, it has become the explicit policy of the Administration to suspend antitrust prosecutions when, in the opinion of the Secretary of War or the Secretary of the Navy, such prosecution would impair war production. (See *New York Times,* March 29, 1942.)

[84] *Investigation of the National Defense Program,* Hearing before Truman Committee, Pt. 6, 77th Cong., 1st sess. [Washington, Supt. Docs., 1942], pp. 1639-40. This volume contains illuminating testimony of several small producers. See also the Truman Committee's *Report Concerning Priorities and the Utilization of Existing Manufacturing Facilites,* Pt. 3, 77th Cong., 1st sess., S. Rept. 480.

[85] See "Concentration of Industry" and "Methods of Concentration," *Economist,* March 8 and April 5, 1941. For a summary of the Board of Trade's very confused explanation of the policy, see "British Concentration of Production," *Foreign Commerce Weekly,* June 14, 1941. One purpose of the policy, to make more efficient use of resources even in the short run, may be commented upon. Let $g(x_1)$ and $f(x_2)$ be the total cost functions of two plants. Then for minimum costs of production for any output $k = x_1 + x_2$, $g(x_1) + f(x_2) = g(x_1) + f(k - x_1)$ must be a minimum, i.e., $g'(x_1) = f'(x_2)$,—marginal cost should be equal in the two plants. The sufficiency condition is

$$g''(x_1) + f''(x_2) > 0.$$

From this condition it appears that in only two cases is it more efficient to concentrate production in one plant: (i) when both plants have falling marginal cost curves, and (ii) when the marginal cost curve of one plant falls more rapidly than that of the other plant

Finally, there are important post-war forces operating to reduce competition. The war's legacy of overexpanded or "sick" industries, to judge from the cases of agriculture and coal, will not lack for governmental assistance which may well take the form of compulsory cartellization. The wave of nationalism may bring into existence new barriers to international trade.

A review of this impressive although incomplete list leads, I believe, unambiguously to the conclusion that the major factor in the decline of competition has been governmental support of monopoly. This conclusion is reinforced when one considers the negative rôles of government, such as the anaemic administration of the antitrust laws until recent times, the weakness of control over corporate charters and activities, and the free play long allowed to the security-market promoters. It must be left to the reader to find a pleasant interpretation of this fact.

V—Other Bases of Monopoly

It would be easy to extend the list of bases of monopoly illustrated by T.N.E.C. material. Among the familiar bases on which evidence is provided, one may mention the ownership of natural resources and transportation facilities;[87] acquisition of assets of rival concerns;[88] the now declining rôle played by the investment bankers;[89] participation in international agreements restricting competition here and abroad;[90] and cultivation of consumer allegiance to particular brands, the allegiance being based proximately on extensive advertising and ultimately on consumers' ignorance of the technical properties of the commodities they buy.[91] But these may be passed over, for the T.N.E.C. follows well-worn paths.

---

rises. Neither condition seems very realistic. (I am indebted to Mr. Herbert Stein on this point.)

[86] See the sulphite pulp allocation plan, *Victory*, January 13, 1942.

[87] On sulphur, see Hearings, Pt. 5, *Monopolistic Practices in Industries, Development of the Beryllium Industry*, pp. 1987 *ff.*; on iron ore, Hearings, Pt. 18, *Iron and Steel Industry;* on pipe lines, Hearings, Pts. 14 and 15, *Petroleum Industry*.

[88] A summary of such cases (which are not subject to section 7 of the Clayton act if assets, and not stock, are acquired), see Hearings, Pt. 5A, *Federal Trade Commission Report on Monopolistic Practices in Industries*, pp. 2361-86; also *Relative Efficiency*, monog. no. 13, Appendix C.

[89] For example, monog. no. 13, Appendix B.

[90] See Hearings, Pt. 5, *Monopolistic Practices*, pp. 1988 *ff.*; Hearings, Pt. 25, *Cartels*.

[91] There is a very useful compilation of information on the phenomena of "monopolistic competition" in *Price Behavior and Business Policy*, monog. no. 1, an exhaustive summary of the research on consumer standards by governmental agencies in *Consumer Standards*, monog. no. 24, and a miscellany of testimony in Hearings, Pt. 8, *Problems of the Consumer*. No general theoretical analysis is given, however, nor are recommendations for social policy explicit.

It may be worth while, however, to consider a less publicized basis of monopoly: monopoly. There is a tendency for monopoly to expand vertically to both market outlets and supply sources and horizontally into the markets for other products. Each of these phenomena will be considered briefly.

The retail outlets for monopolistically produced commodities are frequently cartellized. The situation appears to be most acute when there are a few producers of close substitutes: in their endeavor to secure outlets without resort to price competition, the producers establish their own outlets or offer many special favors to exclusive dealers. This development is well illustrated by the petroleum industry. The major companies have entered retailing on an extensive scale,[92] and in addition they have used wider retail margins, free equipment, free painting, credit card privileges, and threats of erecting competing stations in order to persuade independent dealers to handle only one major company's line of products.[93] There seems to be no doubt but that the competitive position of the smaller refineries has been seriously impaired by these practices. It is also probable that the resultant wastes of "excess capacity" have been great, but these wastes were not rigorously substantiated, let alone measured.[94] The situation in motion picture theatres is similar in many respects.[95]

The monopolistic powers in one product line may be used to coerce acceptance of additional products. Perhaps the most blatant instance was the large meat-packing company which secured widespread adoption of a brand of railroad draft gears in which it had a financial interest by promise or threat of diversion of its patronage.[96] A more pedestrian example is block-booking of motion pictures.[97]

[92] In 1935, eighteen major companies owned 38 per cent of the retail stations. The rise of the "Iowa Plan" of leasing the stations has blurred the distinction between ownership and exclusive contractual relationships with independent dealers.

[93] See the Hearings, Pt. 15A, *Petroleum Industry, passim;* Pt. 16, *Petroleum Industry,* pp. 8907 *ff.*, 9137 *ff.*, 9171 *ff.*; and Pt. 17, *Petroleum Industry,* pp. 9744 *ff.* The legalization of minimum retail margins by state fair-trade practice acts is not discussed. In addition there is evidence of collusion among retailers (Hearings, Pt. 16, *Petroleum Industry,* pp. 9031 *ff.*). An official of the retailers' trade association vehemently expressed his nostalgia for the good old days: "We had a code for the petroleum industry and for the people generally; it was the finest thing in the world, and the little opposition that we had to the Petroleum Code came from the dirty, lousy chiselers who were gypping the public in many ways" (Hearings, Pt. 17, *Petroleum Industry,* p. 9448).

[94] Mr. Swensrud of Standard Oil of Ohio argued that the number of filling stations is not excessive (Hearings, Pt. 15, *Petroleum Industry,* pp. 8678 *ff.*). His arguments do not appear to me to be wholly convincing but they deserve a detailed analysis they did not receive.

[95] See *The Motion Picture Industry,* monog. no. 43.

[96] Hearings, Pt. 5A, *Federal Trade Commission Report on Monopolistic Practices in Industries,* p. 2307.

[97] *Motion Picture Industry—Pattern of Control,* monog. no. 43, pp. 23 *ff.*

Finally, a very important example of the self-propagation of monopoly is vertical integration. Of course when vertical integration rests on technological economies—the stock example is the hot strip mill—the question of monopoly is usually irrelevant.[98] Such economies are historical: technological progress merely leads to a redefinition of the scope of the production process. But it is arguable that most of the important advantages of vertical integration partake of a monopolistic nature.[99]

Two typical causes of vertical integration will illustrate the monopolistic elements which are present. First, if the markets for raw materials or finished products are monopolized or threatened by monopolization, integration becomes a defensive weapon. Thus, the head of a major oil company pointed out the need for backward integration to combat monopolies,[100] and the head of the Beryllium Corporation saw the need for entering the fabricating field because the fabricating company did not wish to disturb its phosphor bronze market.[101] Second, integration on a large scale permits the manipulation of margins of various stages of the production process and hence endows the firm with considerable control over the competitive position of non-integrated rivals. The Hearings on iron ore, semi-fabricated steel, and the petroleum industry pay much attention to the topic, but as usual the witnesses were not questioned in sufficient detail or with sufficient persistence to establish definite conclusions.[102]

University of Minnesota

[98] If the new process is subject to substantial economies of scale, of course, competition will be reduced at that stage and this decline may be communicated through vertical integration to other stages.

[99] The readers of this *Review* will not desire a repetition of the familiar argument that elimination of "middlemen's" profits and the like are illusory gains if the markets for supplies are competitively organized, although of course this point appears in the T.N.E.C. (*e.g.*, Hearings, Pt. 17, *Petroleum Industry,* p. 9749). Managerial economies, one would expect, should normally dictate horizontal, and not vertical, integration.

[100] Hearings, Pt. 14, *Petroleum Industry,* p. 7168. The argument was used to support the thesis that integration leads to competition, which is not unplausible in the light of the witness's concept of competition (*i.e.*, oligopoly).

[101] Hearings, Pt. 5, *Monopolistic Practices in Industries,* p. 2153.

[102] On iron ore—where the witness argued that an integrated concern is merely the algebraic sum of two independent firms—see Hearings, Pt. 18, *Iron and Steel Industry,* pp. 10360 *ff.;* on semi-fabricated steel, see Hearings, Pt. 20, *Iron and Steel Industry,* pp. 10747 *ff.;* numerous charges with respect to manipulation of margins are made against the petroleum industry in monog. no. 39 (*Control of the Petroleum Industry by Major Oil Companies*) but the charges are most inadequately documented.

PRICE AND PRODUCTION POLICIES

By M. M. BOBER

The material of this essay is presented under three heads: first, the economic theory contained in the studies of the Temporary National Economic Committee in so far as it bears on price and production policies; second, such policies in certain specific industries; and third, price and production in the field of retail distribution. That this classification has faults is admitted. It is difficult, for instance, to draw the line between theory and practice; and it may be questioned why the basing point system is placed with the steel industry and not as a problem in theory. Likewise, the discussion of some of the selected industries includes their retailing practices, instead of segregating these practices under the third topic. Nevertheless, this particular organization seems to be a convenient way of blocking out the discussion of a far-flung investigation, and it is hoped that the reader will perceive the convenience as he proceeds.

I—Economic Theory

Viewpoints of the business man. It may be of interest to touch on some of the theoretical views voiced by the business representatives at the Hearings. The business man would not openly be drawn into a discussion of a theoretical flavor, invariably claiming that he is a practical man of experience and facts. Consciously or unconsciously, however, business witnesses gave expression to theoretical opinions.

The changes are rung on the following maxims. Each business is competitive because it is subject to the law of supply and demand, and if a high price is charged, the order is lost to a competitor. The consumer makes the final choice, and there is nothing for the producer to do but to strive to please. No business man will sit idly by and let a competitor get the orders; he will cut the price and get his share. A reasonable price is one which suffices to maintain the properties, cover expenses, carry on research for improving the product, and provide a fair return to the owners of the business, the stockholders. High prices are always attributed to the high cost of materials, to heavy taxes, and especially to wage advances. Poor or modest profits are a demonstration that the price is reasonable. As the volume of production rises, unit costs decline; and in a depression, unit costs rise owing to lower capacity and a higher overhead cost per unit. Advertising creates a mass market, with mass production and lower costs and prices. In

prosperity such prices are to be charged as will make up for the scant profits of lean years. Chaotic competition is destructive and is to be avoided; "stabilization" is to be sought after, above all.

The business man's concept of competition is interesting. It seems to stand less for rivalry and more for coöperation or for the exigencies of doing business in a given set of circumstances. A small concern manufacturing beryllium copper admits that it follows the price published by a leading company, and in a written statement to the committee declares that it "has no alternative except to meet such published prices in order to compete."[1] The negotiations between the largest seller of tinplate (the U.S. Steel Corporation) and the major buyer (American Can Co.) result in a competitive price, in the opinion of high officials in the steel industry; and a smaller firm selling at this price claims to be competing.[2] A trade association reports to the Federal Trade Commission that its objective is "the preservation of competition in its original sense of 'to strive together for common interests.' "[3]

Competition and monopoly. The theoretical discussions by economists are generally confined to elementary problems. The concept of competition is presented in terms made familiar in the last decade; and there is brief mention of oligopoly and the usual exposition of product differentiation. Monopoly is simply referred to as collusion among firms or as the concentration of the supply in one firm; and only once or twice is there reference to measures of the degree of monopoly power.[4] Dr. Clair Wilcox gives in brief paragraphs concise descriptions of nearly a dozen types of competition, such as perfect, pure, imperfect, monopolistic, predatory, potential, cutthroat competition. His inclusion of oligopoly as a form of competition stands, however, without justification. Oligopoly is characterized by him as a situation in which each of the few sellers of a product takes into consideration the price reactions of the other sellers: there is no mention of possible competitive behavior. The resulting price of oligopoly so described will be a monopoly price; and since Dr. Wilcox recognizes cases of monopoly, with monopoly prices, oligopoly should have been

classed as a type of monopoly.[5] There is the customary nonconformity in the use of terms. For example, perfect competition is used at times when pure competition is meant, inasmuch as the definition refers to a homogeneous commodity and many sellers, and without mention of the absence of friction.[6]

Dr. A. C. Hoffman presents two problems not commonly taken up in an elementary discussion. One is a diagrammatic exposition of price policy in an industry of one or a few large firms and many small ones.[7] To each small firm the demand for its product is almost perfectly elastic, but the dominant firm or firms, by varying the output, can affect the price and assume the rôle of price leadership. In their effort to maximize profits as oligopolists, the dominant firms must, however, take into consideration the production response of the small firms to a high price set for the article. The more elastic the supply of the small firms, or the easier the entry, the more are the large firms apt to lose part of their market if the maximization of their profits entails a high price.

The other problem deals with bilateral monopoly,[8] exemplified when both the seller and the buyer are monopolists—the manufacturer selling to the retailer, the owner of raw materials selling to the manufacturer, etc. Dr. Hoffman is unaware that this problem is known in economic literature, and has been examined by Cournot, Edgeworth, Pigou, Wicksell, Bowley, Schneider, and others.[9] However, he deserves credit for recreating independently essential phases of a complicated analysis.

The theory has several aspects and the solutions depend on the assumptions. Dr. Hoffman considers three cases. One, the seller, a manufacturer, sets the price, and the buyer, the retailer, adjusts the quantity. The seller would begin by setting a price calculated to maximize his profits; and if the second monopolist would buy all that the seller would like to sell at the set price, the second monopolist (the retailer) would, with a given demand curve by the consumer, receive a margin merely sufficient to cover the cost of his services. In other words, the first monopolist (the manufacturer) would alone reap the monopoly profit. Accordingly the second monopolist, to obtain some monopoly advantage by enhancing the consumer price above the price which the first monopolist had in view, will purchase less than the first

[6] See, *e.g., Large-Scale Organization in the Food Industries,* monog. no. 35, p. 79.

[7] *Ibid.,* pp. 81-84. (For some of the literature on the subject see G. J. Stigler, "Notes on the Theory of Duopoly," *Jour. of Pol. Econ.,* Vol. XLVIII (1940), p. 522 n. 2).

[8] *Ibid.,* pp. 84, 161-65.

[9] See, *e.g.,* E. Schneider, *Reine Theorie monopolistischer Wirtschaftsformen* (Tübingen, 1932), chap. 2.

monopolist is ready to sell for the maximization of his profits. Worsened by this move, the first monopolist will lower the price to induce the second monopolist to buy more. Marginal cost and marginal revenue are the foci of consideration for both monopolists. The conclusion is that the jockeying will result in a higher price to the consumer and more restricted production than would rule in the familiar cases of one monopolist in a market.

The second case taken up by Dr. Hoffman assumes that the buyer (the second monopolist) sets the price, and the seller adjusts the quantity. The analysis and the conclusions are similar to those of the first case. The third case, briefly mentioned early in the discussion, assumes collusion between the two monopolists on an agreed basis of sharing the profits. Obviously, in this case, the price and the volume of production will behave in the same manner as with a single monopolist. It is noteworthy that, without the use of marginal revenue and marginal cost tools, Bowley offers a somewhat similar approach.[10]

Rigid and flexible prices. The controversy over inflexible prices receives adequate treatment in a well thought-out chapter by Dr. Saul Nelson.[11] He steers a cautious course between the thesis which sees competition in flexible prices and monopoly policy in rigid prices, on the one hand, and the view, on the other hand, which tries to explain price sensitiveness wholly in terms of the market setting. He sees some truth in both but perceives that careful analysis forbids firm generalizations. As a very general proposition, prices are flexible when they are market-determined, that is, competitive. Likewise very rigid prices may point to the presence of monopoly in the traditional or antitrust law sense, when the commodities affected are standardized, or they may imply product differentiation or other aspects of non-price competition, if the products involved are not standardized (pp. 15, 32, 37). But account must also be taken of the specific market situation: *e.g.*, an unchanged price for an article of improved quality is not to be termed inflexible (pp. 27-28).

A study of 111 commodities (p. 38) for 1929-33 discourages a sharp division between categories of goods of small price declines in recession and greatly curtailed production and those of sharp price declines and small declines in production. For durable goods the coefficient of correlation between price and production declines is only —.12, although for nondurable goods it is —.44. There is, however, a broad tendency for small drops in price to be associated with appreciable curtailment of production; and there is a "marked tendency" for such an association as we move toward goods of increasing durability. But we are cautioned

[10] A. L. Bowley, "Bilateral Monopoly," *Econ. Jour.*, Vol. XXXVII (1928), pp. 651-59.

[11] *Price Behavior and Business Policy*, monog. no. 1, Pt. 1, chap. 2.

against postulating a causal connection between such price and production declines: it should not necessarily be inferred that production dropped considerably because the price was not brought down sufficiently. "It happens," says Dr. Nelson, "that the severest price declines during the depression occurred in precisely those industries which produced the most urgent necessities of life, while the smallest declines were to be found among those commodities whose purchase could best be deferred" (p. 40). Necessities would be bought in large quantities even if their prices were but slightly reduced in a depression; and postponable commodities would suffer a great drop in sales even at much lower prices.

It must also be realized, Dr. Nelson insists, that the emphasis on price declines in a depression must extend beyond commodities to such items as rent, wages, interest rates on mortgages, public utility rates, professional fees, and taxes (p. 13). A fall in commodity prices but not in these other particulars may express a distortion in the price patterns as injurious to the economy as the concurrence of flexible and rigid prices for commodities alone (p. 50). He makes the interesting observation that a reduction in prices and charges throughout the economy may come to reflect a settled lower level of incomes, costs, employment and output—without the stimulus to recovery which some are in the habit of finding in reduced prices (pp. 42-43).

At each step statistical findings are presented as illustrations. Fourteen measures of price flexibility, 11 of them developed for this study, were applied to the 784 price series of the B.L.S. index, to test various aspects of flexibility or rigidity during various periods of time, and the results are presented in great detail.[12]

There is a measure of agreement among the investigators for the committee on this subject. Dr. Hoffman is not ready to consider monopoly exclusively responsible for insensitive prices, holding that the preponderance of overhead or variable costs is of paramount significance.[13] Dr. W. F. Crowder, on the basis of an elaborate statistical investigation, comes to the definite conclusion that price and production behavior can best be related to the nature of the particular product and its market and not to the degree of concentration of production.[14] Of course concentration of production is not necessarily identified with aspects of monopoly behavior. Dr. Wilcox alone seems to incline to Dr. Gardiner Means's thesis. After a brief summary of the statistical studies on the subject and of the arguments on both sides, he concludes

[12] *Ibid.*, Pt. 1, Appendix 1.

[13] *Large-Scale Organization in the Food Industries*, monog. no. 35, pp. 113 n. 2, 118; *cf.* p. 71.

[14] *The Structure of Industry*, monog. no. 27, pp. 402-06, 411.

that rigid prices in an industry facing a falling demand and mounting unemployment can only betoken monopolistic behavior.[15]

Nonprice competition. There is a long chapter on this topic.[16] Skeptical about the frequently voiced generalization that competition is in progressive decline, the treatment underlines the conception that there is a redirection of the channels of competition from price to other factors, so that in many sectors, if not generally, competitive rivalry still prevails but with a different focus. The reasons for the trend away from price competition are found in technological progress precipitating the proliferation of varieties and subvarieties of goods, in the distaste of the business man for rivalry in terms of price, in the pressure of the so-called "fair trade" and "unfair practices" laws, and in a changed market structure. The chief avenues of nonprice competition run along quality, brands, service, guarantees, price-lines (to be discussed under retailing), and the like. There is an evaluation of the growing importance of this type of competition in its implications for price policy, the complication of consumers' choices, and social policy. There is no analysis of the impact on the scale of production, costs, monopoly elements, and investment. The chapter is more informational than analytical.

Wage rates and price. An interesting statistical investigation is offered which throws light on the relation between price policy and wage rates and labor costs.[17] Confined to two shoe companies, two paper companies, one cotton textile concern, and the International Harvester Company, and, moreover, to selected articles and over a short period, this study is limited in scope, but it tends to support theoretical discussion of short-run price determination. One must hesitate to translate the diverse facets of the exploration into clear-cut propositions, but the following conclusions of the pertinent parts may be outlined.

Despite the insistent emphasis of business men on high wages as the foundation of high prices, there is less causation between wage rates and labor costs on the one hand and the price of the product on the other than entrepreneurs realize. Price changes precede wage changes in recession and recovery alike (pp. 15-16). In the International Harvester Company, for instance, deliberations on price policy begin with costs as a frame of reference, but controlling consideration is given to a variety of general and specific market conditions so that cost becomes one of many factors (p. 84). For the whole period of 1929-37, changes in the market situation and costs other than the wage bill overshadowed labor costs in price considerations (p. 126).

[15] *Competition and Monopoly in American Industry,* monog. no. 21, pp. 306-07.

[16] *Ibid.,* Pt. 1, chap. 3.

[17] *Industrial Wage Rates, Labor Costs and Price Policies,* monog. no. 5.

In a depression the governing factor is the market setting—the falling demand, the degree of competition, etc.—and once a low price is established pressure follows to reduce labor and other costs. In recovery, costs are somewhat more prominent as a stimulus to rising prices, and wage increases accompany improved prices for the product (pp. 19, 88). If a firm is in a position of price leadership, or if it produces a uniquely differentiated article, more latitude prevails in the formulation of price policy, and then wages, and even costs generally, are more definitely subordinate as price determinants. However, in all cases wages affect profits and the cash position of a firm and are on this account of vital concern to a business, especially in a falling market (pp. 20-22, 40, 120).

In firms in which materials compose a major proportion of the expenditures and are flexible in price, the correspondence between the price of the product and total costs is close; but there should be no inference of a causal link from cost to price (pp. 16-17). In such an instance, as well as in the case where the prices of both the materials and the final product are formed in a competitive market, the profit margin will depend on overhead and labor costs. Accordingly, in a prolonged and severe depression, overhead costs will have a rôle in price policy: to reduce the overhead cost per unit of product by increasing the volume of production, a price will be instituted which will cover variable costs and contribute slightly to overhead costs. Equally, wages will be lowered to permit lower prices and larger volume (pp. 40-41, 50, 52-53).

In periods of rapid and wide industrial fluctuations overhead costs, a large factor, *e.g.*, in the International Harvester Company, have a prominent influence on unit costs. The decline of production in 1929-33 was reflected in rising unit costs, with the consequent pressure for economy in adjustable costs, such as those of labor and materials. The picture was different in these regards in the relative upswing of 1933-37 (pp. 121, 127). But even in these periods there was "lack of any close relationship between changes in season's labor and material costs and changes in prices" of agricultural implements, although company officials stressed rigid costs as one of the principal factors responsible for the failure to reduce prices and maintain production in the former period of 1929-33, and high costs for the advance in prices in the latter period of 1933-37 (70, 87, 89, 91).[18]

[18] Mention is to be made of an elaborate field study (*Export Prices and Export Cartels,* monog. no. 6, Pt. 1), defying summary, which compares export and domestic prices of specified products by anonymous firms. The analytical paragraphs break no new ground; but there is an abundance of examples of selling practices and an outline of the reasons offered by business men for quoting an export price equal to, or higher or lower than, the domestic price.

General observations. It is probably fair to state that the explicitly theoretical formulations touching on price and production policy solve no old problems and raise few new issues, but generally treat well the problem in hand, and with an abundance of factual and statistical illustrations. Certain important omissions must, however, be noted.

First, an investigation of this character needs to give formal and extended treatment to the questions of what constitutes a normal or desirable price pattern in the various segments of our economy; what constitutes a serious distortion in the price structure; and why a distortion deranges our economy, in view of the possible contention that, *e.g.*, with low prices in a given sector like agriculture, what Peter, the farmer, loses as a seller Paul, the city worker, gains as a buyer, and Paul has more money to spend on other goods, instead of Peter. These paramount questions receive only incidental consideration, by Dr. Nelson in his discussion of rigid prices and by Dr. D. H. Wallace in his noteworthy résumé of government regulation of certain industries.[19]

Second, because of the prevalence of price differentiation and non-price competition generally, advertising becomes a central problem in theory. Yet there is scant discussion of the effects of advertising on the scale of production, costs, investment, and prices.

Third, there is little or no analysis of such relevant problems as the components of cost and the behavior of costs in the firm and the industry; of the theory of oligopoly; and of the influence of commodity speculation on prices.

II—Selected Industries

When turning to the sketch of price and production policies in specific industries—construction, milk, oil, and steel—it is necessary to remember that the chief objective of the committee's investigations was the concentration of economic power, that all discussion was primarily oriented to this objective, and that aspects of price and production, far from finding a focus of their own, are auxiliary to the central purpose. One must not expect special studies of price and production in given periods of time and in given places, in relation to unique circumstances and market structures. Price and production behavior is, rather, embedded in a context of description of monopoly and competition; and this is more true of the milk and oil industries than of the construction and steel industries. The scrutiny of each industry seems to have its center of gravity in the proposition that the

[19] *Economic Standards of Government Price Control,* monog. no. 32, pp. 494-96, 500-04. See also *Technology in Our Economy,* monog. no. 22, pp. 190-94.

cause is monopoly and the cure is competition. This circumstance explains the tenor of the account that follows.

The construction industry. The construction industry[20] exhibits three related maladies. First, like all durable goods industries, it is expected to make its contribution to recovery with the termination of a recession; and yet in the revival of 1937 this industry notoriously lagged behind both in employment and in the dollar value of the product. In the peak of 1937 durable goods industries reached the level of employment of 1929, whereas the construction industry, as well as the industries preparing materials for construction, failed to reach such a level, varying from 65 per cent of the 1929 level for lumber millwork to 87 per cent of this level for plumbers' supplies.[21] Second, throughout the period of 1929-37, building materials were higher in price than either capital goods generally or the B.L.S. index of commodities,[22] thus contributing to the impairment of economic activity associated with marked dislocations in the price structures of the different segments of our economy.

Third, the residential house building industry is marked by a distressing disequilibrium between supply and demand. The volume of low priced housing in demand by the population obviously far exceeds the volume of high priced housing; nevertheless, the amount of building from year to year is remarkably small in the former class and remarkably large in the latter. Forty-eight per cent of the homes built in 1934 were valued at between $6,000 and $10,000, but only 15 per cent of city families could afford to rent or buy such houses; 48 per cent of city families can afford to buy or rent homes selling at $4,000 or less, but only 20 per cent of the houses built are in this category.[23] For the period of 1922-38, the volume of private house building traces a curve like that of the volume of high priced (over $750) automobiles sold, and not at all like the curve of low priced automobiles sold.[24] Stated generally, at prices which equilibrate supply and demand for the masses of the poor, the housing obtained is of demonstrably inadequate character. In the famous phrase, one-third of the nation is ill-housed.

Many are the factors responsible for these conditions, and the in-

[20] Hearings, Pt. 11, *Construction Industry; Toward More Housing*, monog. no. 8; *Geographical Differentials in Prices of Building Materials*, monog. no. 33; *Competition and Monopoly in American Industry*, monog. no. 21, pp. 287-89.

[24] *Ibid.*, p. 4985.

vestigations pay attention to heavy taxes, high interest rates in house finance, and inflated land values. Chief emphasis is given, however, especially by the economists who summarize the situation, to two circumstances: obsolete methods of production and monopolistic prices.[25] While the production of most building materials is characterized by modern methods, the actual construction of houses is largely reminiscent of the handicraft days. The building process involves numerous distinct parts and many independent crafts and retailing operations, often without the integrating management of an experienced entrepreneur: the building of many a "home" is supervised by the housewife. The small size of the enterprise, the general lack of technological improvements and standardization of materials, poor, uncoördinated management, the tradition-ridden and parochial attitude of the public and city governments alike, combine to stamp the house building industry as one of low productivity and high costs.[26]

The second circumstance is the almost complete subjection of the industry to varying degrees of monopoly power. Oligopolies and strong national trade associations in the supply of materials are paralleled by the local monopolies of contractors, dealers and labor, with high and rigid prices, wages and costs almost wherever one turns. There is, in addition, vigorous opposition, by labor and the small local business men alike, to labor saving devices, to innovation and experimentation, and to the enlargement of markets and the scale of production. The industry tends to support the affirmation that the monopolizing spirit is not the unique attribute of big business, but is to be found as well in the man in overalls and in the village tradesman.[27] Reinforcing the element of monopoly is the fact that a house, consisting of a multitude of parts and involving many classes of labor, reflects a joint demand. Accordingly the seller of any given part, or any group of laborers, may feel that a low price for the individual product or service, constituting but a small part of the cost of a house, will not have a stimulating effect on house building. The seller considers the demand for his product or labor very inelastic. No one agency will be induced to diminish the price in face of a declining demand unless all the agencies essential to the industry will simultaneously reduce their prices.

Some aspects of the price and production data for the industry deserve comment. For the period of 1929-38, charts show an inverse relationship between nonresidential construction and the "exchange

[25] *Ibid.*, testimony of T. J. Kreps and W. Thorp; *Toward More Housing*, monog. no. 8.

[26] *Toward More Housing*, monog. no. 8, pp. 61, 130, 133.

[27] *Ibid.*, pp. 134-35; Hearings, Pt. 11, *Construction Industry*, testimony of W. Thorp and T. Arnold.

value," or barter terms of trade, of iron and steel; and similarly between residential construction and the "exchange-value" of lumber and of brick and tile. Construction declines in volume as the value of structural materials rises, that is, as more goods have to be offered in exchange for materials.[28] The discussion of these charts at the Hearings suggests a causal connection between these two variables, clearly implying that if in a recession the prices of building materials and of capital goods in general fluctuated in accord with other prices, building and durable goods industries would play a prominent and initiating rôle in recovery, as was the case before the past two decades. However, we do not know enough about business cycles to accept this inference. More than one theory of the trade cycle suggests that the impulse to recovery will have to come from more directions than lower prices for capital goods.

A separate monograph[29] presents a very elaborate collection of figures for 37 building materials, from asphalt to white lead, in 50 cities, in every state, during the period from January 1935, to September 1939. Actual prices, wholesale and retail, and corresponding monthly price indices are offered for each of the nine geographical regions of the country. Only a few summarizing remarks can be given here. The most common types of geographical price structures used are the freight equalization, the multiple basing point, and the zone systems. The national trend of wholesale prices of these commodities was upward for the period, with a considerable rise in 1936-37. During any part of this period some commodities were not with the trend but remained stable or moved in the opposite direction. The retail prices of each article followed the trend of its wholesale prices, but the fluctuations were narrower. Of the regional trends, some conformed to the national curve, and others departed from it. In general, regions closer to the producing areas of certain articles enjoyed lower prices, while far-off regions showed the disadvantage of transportation costs. Thus the retail price of sand, gravel and crushed stone was consistently lower in New England and in the Rocky Mountain and Pacific regions than in other areas. For most articles, however, except, *e.g.*, fir doors, prices were high in these latter two regions and low in the Northeast. The wholesale prices of insulation board and plumbing fixtures exhibit, for carlot shipments, no geographical variation, since the practice is to allow full freight. Where, as in the case of lime, there is a wide geographical distribution of small plants, the pricing practices display no discernible pattern for the country. Where retail prices tended to be

[28] Hearings, Pt. 11, *Construction Industry*, pp. 5447-52.

[29] *Geographical Differentials in Prices of Building Materials*, monog. no. 33.

high, the margin to the retailer was high. This means that margins were high away from producing areas. Higher margins seem also to be associated with inflexible retail prices.

The investigations of this industry offer abundant new data on the prices of building materials, samples of the costs of building operations and their components, figures on wage rates in building trades, and statistical illustrations of the disequilibrium between the supply and demand for housing. There is little or no discussion of such topics as the so-called long cycles in the industry; the evidence that building anticipates a recession; the effects of war on building; and the fluctuations in and the unique problems of the construction industry aside from city housing, *e.g.*, activity in the field of public utilities, factory construction, or rural building. It is worth noting that, while the T.N.E.C. studies establish that labor costs constitute a considerable proportion of the total costs of construction, there is a disposition to tone down the effect of monopolistic practices of labor on building costs.

The milk industry. In the milk industry, while the two leading companies, the National Dairy Products Corporation and the Borden Company, do not control over 12 and 8 per cent, respectively, of the country's fluid milk not consumed on the farm, in many cities 4 or 5 large distributors handle from nearly 60 to 90 per cent of it. There is no evidence of price competition among the oligopolies, but not a little evidence of price setting and of higher prices than those charged by small independents.[30]

Milk sold to the distributors and processors is not treated as a homogeneous product. Class I milk is bottled milk used as a beverage; it needs greater care and brings a higher price to the farmer. Class II, and further classifications, represent milk used for dairy products, like fluid cream, butter, cheese, ice cream, and condensed milk: it is commonly referred to as surplus milk.[31] Under competitive conditions all the milk would sell at a price in accordance with its marginal use; but both producer and distributor, having some degree of monopoly advantage, prefer to protect the price of fluid milk at a comparatively high level and divert the "surplus" milk at lower prices to manufactured dairy products.

The method of distribution to the consumer is a bone of contention. The distributing companies—and truckmen's unions—prefer the daily doorstep delivery, in the opinion that it assures a large and steady demand, and that the housewife will often neglect to buy milk if she has to go for it to the store or depot. Such delivery entails inevitable waste. A study of the situation in Milwaukee for March 16, 1934,

[30] Hearings, Pt. 7, *Milk Industry*, pp. 2763, 2851, 3137, 3196-97, 3202-04, 3221.

[31] *Ibid.*, pp. 2960, 2965.

revealed that in 1,020 blocks an average of 6.8 concerns delivered milk in a block. In one extreme case, 17 concerns served one block. Nearly 1,000 individual premises had "duplication of delivery."[32]

The price of milk to the consumer stood high and rigid, even during the depression of the 1930's. But the farmer's share of each dollar spent on dairy products declined from 52 cents in 1923, which is generally taken to mark the beginning of the growth of the large processing and distributing companies, to 35 cents in 1933; and the processor-distributor's share rose correspondingly.[33] Whether, and to what extent, this represents exploitation of the farmer by the distributor cannot be judged without an analysis of the supplies of milk and of the costs of processing and marketing in this period; but such data are not presented. The price paid the farmer and the margin secured by the distributor are not necessarily at the expense of each other. A large supply of milk may depress the price to the farmer; while rising costs of processing and marketing may simultaneously induce high margins to the seller of the finished product. In fact, a large supply of milk may enhance the demand for the services of the distributor. The complaint is voiced that the large dairy companies are especially interested in pushing the much advertised and differentiated manufactured milk products, like cheese and canned milk, and for these goods, although they are inferior as a food to milk, the market has grown and the price has declined.[34]

Arrays of figures are presented here and there to indicate the price behavior of fluid milk in various towns and at various times. Unfortunately, the significance of the data is considerably diminished in view of the lack of parallel studies of costs in these localities and of the various other aspects of the respective market patterns.[35]

Some of the government experts seem to be impressed by the experience of an independent dealer in Detroit[36] and by studies in Milwaukee, both indicating that milk can be sold at 6 cents to 8 cents a quart at depots on the cash-and-carry basis. Indeed, while some of the experts are content with the suggestion that a vigorous milk industry is contingent upon the restoration of competitive conditions therein, one of them, Dr. F. C. Howe, sees a definite panacea in the depot method of distributing milk.[37] He is of the opinion that a "free competitive system" would "automatically" result if "milk flowed

[32] *Ibid.*, p. 2784.

[37] *Ibid.*, pp. 2814-32, 3134.

freely through the pasteurization plant at a custom or tolling charge determined by cost and was available to all buyers."

It is difficult to share such optimism. We are not told about the agency that will negotiate with the farmers for the supply of milk for the depot, what assurance there is that this agency will not strive for large profits, and how the farmers will dispose of their surplus milk. We need to know the relative elasticities of demand for fluid milk and for the varieties of dairy products if we are to gauge the effect of a price change in any one class of milk upon the competition, or the diversion, from the other classes, or upon the incomes of the farmers. Account has also to be taken of the cost of building and managing pasteurization plants and properly located depots in a large city, of scientific experimentation and educational advertising, and of doorstep delivery. Without such studies it is difficult to estimate the degree of power exercised by the bilateral monopoly (*i.e.,* the customary bargaining between the farmers' coöperatives and the large distributors) in the industry, the possible reductions in the price of milk and the concomitant rise in the consumption of it, and, generally, the repercussions of alternative methods of distributing milk.

Since 1933 the milk industry has joined the ranks of enterprises regulated by federal or state authorities, and the experience, treated in a separate study[38] which deals also with the regulation of the more commonly recognized "public utilities" in three sample states and of bituminous coal, gives some idea of the price and production policies of regulatory bodies. The inquiry is detailed and scholarly, and Dr. D. H. Wallace's hundred-page summary is shot through with theoretical considerations and broad views of social policy. The study approaches the problem from three angles: the level of prices set by regulation; the price structure as among the different classes of goods; and the impact of the prices upon employment.

The foundation of federal regulation of milk prices is the celebrated principle of "parity prices" to farmers. In a number of milk markets to which the interstate commerce clause applies the farmers' coöperatives, the large distributors and government authorities collaborate in setting the price of Class I and Class II milk (cream). It has proved impossible to raise the price to the "parity" level, principally because of the competition of outlying areas and the diversion of Class III, that is, manufacturing milk. However, owing to the restrictive measures of the coöperatives and the sanitation authorities, prices have been raised appreciably. The distributors' margins have remained unaffected, and the full incidence of federal regulation seems to have been on the consumers' pocketbook.

[38] *Economic Standards of Government Price Control,* monog. no. 29, Pts. 2 and 4.

All the five milk regulating states investigated in this study—California, Indiana, New York, Oregon, and Wisconsin—set minimum prices to the farmer on Class I and Class II milk, and in some markets in some of these states, on the other classes as well. None sets maximum prices. All states fix the resale price to the consumer, evidently to avoid impairment of the price structure set for the producer; but New York abandoned this policy in 1937. In all states, especially in California, attention is given, in varying degrees, to cost calculations. In California the objective is to establish a differential between fluid and manufacturing milk commensurate with the difference in costs in preparing the two types of product; but in the other four states the principal goal is to enlarge farmers' incomes. In three of these states there is some control of entry, and one of these three, Oregon, has formulated a definite scheme of restricting output. In most of these states, notably Indiana and New York, procedure relies on bargaining between producers and distributors with assistance from the public official; and in all of them, except California, objectives and standards are vaguely expressed in such terms as "fair price," "orderly marketing," "reasonable profits." The available evidence indicates that state control has resulted in advanced prices to the farmers; but there is precarious evidence regarding distributors' margins. After a consideration of the various aspects of a transfer of income from one group of persons to another, the conclusion is reached that raising milk prices to the farmer failed to contribute to general recovery.

The petroleum industry. The consistent theme running through the extended investigations of the petroleum industry[39] is the power and practices of the twenty large integrated companies, commonly referred to as the major companies, and the sad plight of the independents. Little is to be found on price and production structures.

The production of crude oil exemplifies alike the difficulties of unrestrained rivalry and the inadequacies of partial planning. For nearly a decade and a half after the First World War periodic overproduction, price wars, waste, and violent fluctuations in costs and earnings characterized this field, where entry is free and investment and the scale of operations small. The situation was aggravated by the law of capture and the disregard of underground oil for the legalities of the surface boundaries of ownership. In response to the demands for conservation and the "stabilization" of the industry various states adopted proration laws, restricting the production of crude with some regard to

[39] Hearings, Pts. 14-17, 14A, 15A, 17A, *Petroleum Industry; Control of the Petroleum Industry by Major Oil Companies,* monog. no. 39; *Review and Criticism on Behalf of Standard Oil Co. (N.J.) and Sun Oil Co., of Monograph No. 39 with Rejoinder by Monograph Author,* monog. no. 39A.

an estimated demand. These attempts at planned production have been haphazard and of varying degrees of earnestness, and the complaints from the small independents have been numerous. An obvious difficulty rests on the fact that the amount of oil demanded is a function of the price, and price, even in a wayward industry like oil, depends at least partly on cost, which in turn is governed by the amount produced by an entrepreneur: this amount is determined by the quota, but the quota is fixed by the estimated demand. The planner's lot is not a happy one.

The production of crude is to this day a blend of competition and monopoly. Many independents prospect, discover wells and operate them;[40] but much of their land is leased by the major companies. The majors produce one-half of their crude, and they buy from the independents more than they need for refining, selling the excess from time to time in order to influence the market.[41] A small group of large buyers, they confront the many independent sellers with a price set by a leader or by explicit agreement. Nevertheless the price for crude has not been inflexible; during the period between 1926 and 1933, California crude had 19 changes in price, Kansas crude had 45, and Pennsylvania crude had 60. During a period of relatively great economic activity, 1926 to April 1929, the corresponding frequencies of price changes were 7, 18 and 24.[42] However, between 1934-38, prices seem to have been very rigid.[43]

In the movement of crude to the refinery and of gasoline to the consuming markets the pipe line is essential; and since transportation by rail is twice as expensive, the majors, who own the pipe lines, have monopoly power over the independent shipper. The independent is compelled to sell his crude to a few buyers; or to ship over the pipe lines at a profit to their owners; or to build refineries near the oil fields and operate on a small scale and away from the consuming centers.[44] From the refinery the gasoline is moved, in tank cars and tankers, by refiner and jobber, to the bulk station, and from there it is distributed to retailers. The independent refiners without retail outlets sell the gasoline at prices based upon those posted in the trade journals: this is the spot market, sensitive, fluctuating and subject to manipulation. Independents and jobbers who ship the products over pipe lines are subject to a multiple basing point system, under which the rail rate is

charged to destination.[45] There is evidence that the majors exert pressure on the railroads to adjust the rates unfavorably to competitors.[46]

The retailing of gasoline expresses the same type of monopolistic competition as is apt to be observed in any other occupation representing differentiation of service, free entry, little requisite experience, and small scale investment. The difference between the properties of many of the gasoline brands are hardly outstanding, yet the brands are intensely advertised as unique creations, and each brand seeks individual outlets.[47] Most of the gasoline stations—85 per cent of them[48] —and therefore most of the dealers are controlled by the majors, either as employees or under the lease system known as the Iowa plan. In either case the sale of competitive brands is discouraged by subsidies and penalties.[49] The sequel is that there are too many gasoline stations, too many of them are of needlessly expensive architecture, too many operate under capacity, and the expense of retailing as well as the price to the consumer are too high.[50]

There is evidence of retail price setting by the majors, by collusion or price leadership.[51] It seems that at least one retailers' trade association is far from rising above similar practices; and there have been examples of outright agreements, by majors and independents alike, to fix wholesale and retail prices.[52] A local price war may develop owing to one or more of such circumstances as the following. A new gasoline station may decide to lure customers with a low price. A seller of unbranded gas may start cutting the price. An ambitious dealer may attempt to make money by larger sales at a reduced price. A rumor may get around that a neighboring station is making secret price concessions to customers. A company agent may drop the remark to a lessee that his gallonage is below what it should be because he is not sufficiently competitive, and the lessee, fearing the cancellation of

the lease, strives to raise his sales.[53] During the period between 1926 and 1933, gasoline prices were, by every measure, definitely flexible.[54] According to the testimony of representatives of the industry, the retail price of gasoline between 1923 and 1937 showed a downward trend and was consistently below the B.L.S. index.[55] However, the earnings of 24 companies in the industry rose by 47 per cent in 1937 over 1923, while the income in all manufacturing industries advanced by 8.8 per cent, and the national income by 4.1 per cent.[56]

In evaluating data on price and earnings it is well to remember that, except when the station attendant is explicitly an employee of a company, the incidence of price reductions in gasoline is at least in part on the leasing dealer. Further, while all the marketing phases, from the refinery to the consumer (with the station dealer as an employee of a company), are frequently unremunerative to the majors, what matters to them is the net earnings on the integrated operations as a whole, and such earnings have made a good record.[57]

The iron and steel industry. The best study of price and production policy in any of the T.N.E.C. surveys is connected with the examination of the iron and steel industry. Prior to the Hearings, the U. S. Steel Corporation prepared a number of important analyses, under the direction of Dr. T. O. Yntema, dealing primarily with demand and cost phases of steel and defending the basing point system.[58] In their turn the experts for the committee subjected many of these studies to a searching criticism.[59] There is room only for a sketch of some of these studies, but not for comments on the testimony of business men at the Hearings,[60] which was, however, scarcely different in tenor from the testimony at the Hearings on the other industries.

On the demand for steel two studies presented by the U. S. Steel

[60] Hearings, Pts. 18, 19, 20, 26, 27, *Iron and Steel Industry.*

Corporation are of special importance. One study examines the demand for steel in the major steel consuming industries.[61] The cost of steel used in making the products concerned constitutes 10 per cent of the price of automobiles; from 3.4 per cent to 13.9 per cent of the retail price of canned goods; 5 per cent of the value of transportation service; 4 per cent of the cost of a frame house; and 30 per cent of the cost of a steel bridge. The average proportion of the cost of steel to the price of the finished product is taken to be 10 per cent. Thus a 10 per cent reduction in the price of steel will be translated into a 1 per cent reduction in the price of the finished product. The elasticity of the demand for these finished products, of which steel is a component, is "possibly less than 1 or 2." Accordingly, a 10 per cent reduction in the price of steel will reduce the price of the product by 1 per cent and raise the sale of the product, and the consumption of steel, roughly by only one or 2 per cent: the demand for steel is very inelastic.[62]

The second study explores the elasticity of the demand for steel on the basis of a series of steel data for 1919-38.[63] The purpose is to correlate respectively production, shipment, and bookings of steel with such factors as the price of steel, general industrial activity, consumers' incomes, and industrial profits,[64] in order to test the relative strength of the impulses behind the demand for steel. The analysis is abstruse, with adjustments necessitated at each step and with assumptions and hypotheses erected upon assumptions and hypotheses. The final conclusion is that general industrial production, industrial profits and consumers' incomes exercise a primary influence on variations in the amount of steel sold, but that the price of steel is a minor factor; and that the elasticity of the demand for steel is only 0.3 or 0.4.[65]

Another study looks into the relation between output and costs, and subjects to econometric analysis the cost and output data of the U. S. Steel Corporation and its subsidiaries for 1927-38. To eliminate the influence on variation in costs of other factors than output, the total costs of each year were adjusted to the levels of prices of materials, wages, interest rates, taxes, and pensions prevailing in 1938; and since the corporation produces numerous different products, they were all reduced, by a scheme of weighting, to a homogeneous tonnage for each year. The scatter diagram for these annual adjusted costs and

[61] Hearings, Pt. 26, *Iron and Steel Industry*, p. 13589; and Exhibits nos. 1413-1415, *ibid.*, pp. 13981-14016.

[62] *Ibid.*, pp. 13592-93.

[63] *Ibid.*, pp. 13594, 13928.

[64] *Ibid.*, pp. 13594, 13921-22.

[65] *Ibid.*, p. 13927.

outputs is fitted by a straight line sloping to the left. This line points to results contrary to common understanding of the relative magnitudes of the fixed and variable costs of producing steel. The fixed costs are found to be only 182.1 million dollars a year, while the variable costs are as high as $55.73 per ton and are, moreover, constant per ton for a production capacity ranging from 18 to 90 per cent.[66]

The implication of these studies is clear: a reduction in the price of steel during a recession would serve little purpose except inflicting on the firm considerable losses. Specifically, even if the elasticity of the demand for steel is assumed to be unity, a 10 per cent reduction from the 1938 price of steel would occasion a loss of 43 million dollars, and would require a 48.8 per cent rise in production for the producer to break even.[67]

These studies have been criticized at each step by the experts for the committee,[68] but only a few points can be mentioned here. It was pointed out that the price elasticity of steel has been found low on the assumption that the other conditions are constant. But the increased steel output stimulated by a reduction in the price, especially if the reduction is substantial, would, by its impact on investment, employment, and income, encourage alike general business activity and the demand for steel, thus rendering this demand much more elastic. It was also indicated that a general revival of business is bound to arrive when several durable goods industries cut their prices simultaneously; that the use of annual data and weighted tonnage, covering up the varying characteristics of the individual products, tends to minimize the elasticity of demand;[69] and that the elasticity cannot be assumed to be constant for the period under study since it varies with the size of the price reduction, with the phase of the business cycle, and with the expectations of profits.[70] These criticisms have point, but it is doubtful that a price reduction in the steel industry alone can have a control-

[66] *Ibid.*, pp. 13595, 14034, 14051, 14065.

[67] *Ibid.*, pp. 13598, 13602-04, 14064-66.

[68] Hearings, Pts. 26 and 27, *Iron and Steel Industry*, testimony of L. Bean, M. G. de Chazeau, M. Ezekiel, M. Taitel, H. E. White, and W. B. Wooden, and the replies by T. O. Yntema.

[69] Hearings, Pt. 26, *Iron and Steel Industry*, pp. 13632-34.

[70] *Ibid.*, pp. 13635, 13671. The Federal Trade Commission's pamphlet on the basing point system makes an invalid deduction concerning the demand elasticity for steel. Referring to a statement by the U. S. Steel Corporation (*The Basing Point Problem*, monog. no. 42, pp. 46-47) that the demand for the steel of an individual producer is very elastic, since if he shades the price customers will readily shift to him, the pamphlet asserts, "It would seem impossible for an inelastic total demand to be built up out of a series of particular demands that are elastic" (monog. no. 42, p. 125). According to such a view, the total demand for wheat, or any other commodity under pure competition, is perfectly elastic.

ling effect on industrial activity. Also, a concerted price cut by several durable goods industries is apt to provide a strong stimulus indeed, but the suggestion is hardly a valid criticism of the corporation's argument.

More incisive are the criticisms of the cost-volume studies.[71] It is pointed out, among other things, that the income statements of the corporation for 1927-38 are not adapted to the purposes of a cost-output investigation; that the period is too short and, in the critical area on the scatter diagram, there are too few points to fit a reliable line of regression; that the fit on this scatter diagram may properly be curvilinear, pointing to higher fixed costs and lower variable costs; that the adjustment of the data is questionable here and there; that the weighted tonnage is a precarious concept although the technique employed is unimpeachable; that the costs of production are high on account of the possible inefficiency of the oversized corporation; and that the corporation may not typify the industry as a whole with regard to fixed and variable costs.

Doubt is imported from still another quarter. A careful study was made of the relation between the size of a shipment and the magnitude of price concessions in the steel industry, based on ample data for February 1939, supplied by the industry in response to a special questionnaire.[72] It is revealed that the price concessions mount strikingly with the size of the shipment.[73] Steel production in February 1939 was nearly 55 per cent of capacity, and at such capacity the proportion, in the U. S. Steel Corporation, of fixed costs to total costs is 25 per cent.[74] Since according to the corporation studies variable costs are constant and in this instance they amount to 75 per cent of total costs, it seems doubtful that, to get large orders, the industry could afford to diminish mill nets by one-half or more per ton—provided we emulate the corporation and imply that its costs are typical of the industry and that 1938 cost conditions argue for those of February 1939. According to this study, more plausible would be the explanation that variable costs are not constant, but decline as orders and output rise.[75]

In general, it is easy to agree with Dr. Isador Lubin when he remarked at the end of the Hearings on the corporation studies that "the same job might have been done by somebody equally well with a

different set of assumptions and different set of methods and gotten entirely different results."[76]

There is lastly the controversy over the basing point system, as warm and as indecisive as ever.[77] There is no intention here to join the lists, but a few remarks may not be out of place. The attitudes of the corporation and the Federal Trade Commission are a study in contrasts. The corporation pamphlet perceives noncompetitive conditions in the industry, but denies monopolistic practices. The Federal Trade Commission perceives monopolistic practices, but ignores the underlying noncompetitive conditions in the industry.

The corporation pamphlet makes much play of the idea that pure competition[78] is an abstraction not exemplified in the world of actuality, implying that the departure of steel from this abstraction is a normal occurrence in industry. The pamphlet does not recognize that, since the essence of pure competition is a price without an ingredient of monopoly, and since, equally, any such price situation is tantamount to pure competition, departures from pure competition betoken a degree of monopoly power.[79] The pamphlet consistently insists that the basing point system is the expression of competition, and nowhere is there mention of a trace of monopoly in the industry. In other words, pure competition is an abstraction, and yet the steel industry, denying the taint of monopoly, is the embodiment of the abstraction. The pamphlet, moreover, considers identical delivered prices as an index of competition. Identity of prices, however, may be associated with duopoly, oligopoly, price leadership, nonprice competition, collusion or pure competition. Only a scrutiny of the conditions producing the identity will reveal the substratum of competition or monopoly.

The claim is made, further, that the basing point system is the natural outgrowth of the unique circumstances describing the industry. This claim is inadequate if it means that, without collusion, the conditions of the industry prompted each steel firm to the basing point system as we know it; just as oligopolists may be induced independently to charge a monopoly price. The claim can at best imply that the basing point system is not the child of the desire of wayward people to be antisocial, but is rather, at least in part, an adjustment to a difficult situation. Analysis and recorded facts unite to suggest that the basing point system could not have emerged and could not endure without monopoly elements somewhere in the situation.[80]

[76] Hearings, Pt. 26, *Iron and Steel Industry*, p. 13715.

[77] *The Basing Point Problem*, monog. no. 42.

[78] "Perfect competition" is used, but the explanations indicate that pure competition is meant. See *ibid.*, pp. 43-44 and notes.

[79] *Ibid.*, *e.g.*, p. 45.

[80] *Cf. ibid.*, pp. 94-105, 107-109.

On the other hand, the insistence of the Federal Trade Commission on making the steel industry competitive by substituting mill base quotations for the basing point system forgets that the proposal, failing to eradicate the underlying features of the industry which engender monopoly, merely seeks to establish the semblance of competition without achieving the substance of it. It is evident that the steel industry is dominated by a few large corporations. It will not be possible to prevent those gatherings for "merriment and diversion" of which Adam Smith complains and at which high f.o.b mill prices can be set. Even without meetings, price leadership or the regard of each seller for the price and production reactions of the other sellers is calculated to institute monopolistic mill prices. Under competition only mill base prices govern; but not every situation in which mill base prices govern is competitive.

Other industries. Some attention was given at the Hearings to the beryllium[81] and liquor[82] industries, with emphasis on patents, the habitual practices of leading concerns, collusive price setting, and, in the case of liquor, the multitude of brands. There is also a monograph[83] summarizing an older investigation by the Federal Trade Commission of the natural gas industry, including natural gas pipe lines, with a few pages on aspects of inquiries by the commission into the agricultural implement and motor vehicle industries. This monograph, of rather poor composition, has little of arresting importance on price and production.

III—Retail Distribution

The position of the consumer. Obviously it was not the intention of the investigations to prepare a treatise on retailing, but scattered throughout the studies we meet problems belonging in this field. There is a volume of Hearings[84] on the plight of the consumer confused by the stress on brands and makes, by the tinselled catchwords and grandiose sales promotions.

The story is familiar. He is confronted in the city of Milwaukee with dozens of brands of canned milk, 142 brands of coffee, 95 brands of tomato juice, 225 brands of canned peas, 107 brands of peanut butter.[85] Tomato juice, according to another consumer witness, presented itself in one store in 21 different containers, 11 brands of varying sizes and

volumes, and 15 different prices.[86] How to translate the diversity of quantity, quality and service into comparative price equivalence, for a rational choice, is a problem of calculus defying the knowledge and patience of the average consumer. Even simple products like salt and sugar come packaged, branded and advertised so that choice by price alone is precluded.

Brands and price are inadequate guides. German silver has no silver in it, and French ivory is not ivory. Like the Holy Roman Empire to Lord Bryce, French linen is neither French nor linen. "Beaverette" means rabbit skin.[87] The Bureau of Agricultural Economics tested samples of brands of canned fruits and vegetables; and the more specimens of a given brand were tested, the greater was the variation in the grades of quality.[88] Different brands or types of apparel, tires, bedding, drugs or desks are of identical quality but sell at different prices.[89] Higher priced milk has been found to be no better than lower priced milk; and better goods sell at lower prices than inferior goods. The consumer is victimized by false certificates and testimonials, by spurious experts and foundations, and by publications alleging that advertisements in them are trustworthy.[90] How representative such examples are of business practices it is hard to tell. Witnesses and writers are prone to cite outstanding cases; and the investigations under consideration probably do not give a balanced picture.

Proper buying demands calculation and experimentation. Large business concerns and institutions like hospitals and universities employ expert buyers. But a major proportion of the world's buying for the consumer's utility is done by the housewife, who, as Professor Wesley Mitchell once remarked, "is not selected for her efficiency as a manager, is not dismissed for inefficiency, and has small chance of extending her sway over other households if she proved capable."[91] A large monograph is devoted to the problem,[92] but the emphasis falls on providing an exhaustive inventory of the organization and activities of government and private agencies for testing products, procuring their own needs, and directly or indirectly helping the consumer. There is insufficient

integration and evaluation of what is being done for the wayfaring consumer by private agencies, by general education, and by the Federal Trade Commission, and there is a somewhat inadequate analysis of what remains to be done for a greater accomplishment. Recommendations run in the following terms: an investigation of the agencies which rate commodities; a study of the effects of resale price maintenance legislation; standardization and labeling of goods; and a government agency of consumer service.[93]

Chain stores. In his monograph on the food industries Dr. A. C. Hoffman summarizes various studies on food chains. Several investigations confirm the view that chain prices in food are distinctly below those in independent stores although this does not necessarily hold of each particular article. Individual chain stores are allowed to depart from the set rules pertaining to mark-ups, for the purpose of meeting local conditions, and a price war may be initiated to crowd out an independent. The emphasis is commonly on price appeal; but there are instances of nonprice competition in the form of advertising and impressive buildings. Prices are flexible, more so in staple goods than in specialties.[94]

The Federal Trade Commission charges that chain mass buyers browbeat the sellers and small processors into unwarranted price concessions and allowances; that they employ the "loss leader" device; and that they pay lower wages than independents do. Dr. Hoffman stresses, and quite properly, such factors as the superior efficiency of management in chain stores, division of labor and specialization of functions, large scale buying and selling, the integration of wholesaling and retailing, and the employment of modern methods generally, all contributing to greater productivity and lower costs. He disposes of the low wage argument by indicating that the sample on which it is based is alike small and unrepresentative.[95]

The question whether prices and margins in retailing in general are competitive receives considerable discussion, and the conclusion is that the retail trade is competitive. Dr. Wilcox[96] offers several lines of evidence in favor of this thesis: the large number of retail units in relation to the population in cities large and small; the very small size of trading establishments, although there is a degree of concentration; the competition of mail order houses, chains, department stores, independent

retailers, consumers' coöperatives, etc.; free entry, in view of the small requirements of capital and experience; unusually low earnings for the trade as a whole, although the large corporations reveal high earnings; and a high rate of mortality.

The evidence is impressive, but a caution or two may be pertinent. The presence of large numbers is deceptive. Retailing is uniquely a matter of local markets, and local markets may be noncompetitive, as Dr. Wilcox realizes when he states, on another page,[97] that the presence of many sellers locally or nationally, "affords no guarantee that active competition will prevail." Retailing exemplifies differentiation of product with free entry, overinvestment and undercapacity, yielding a monopoly price without, however, a monopoly profit. Further, the low earnings of the trade as a whole may reflect, at least partly, inefficiency, old-time methods, and small scale operations translated into low productivity and high costs of rendering the service.[98]

Dr. Hoffman argues similarly and more extensively to the effect that food chains are competitive concerns. Among the several indicia of monopoly which he examines is the consideration that the sales of the chains constitute a smaller percentage of total sales for the country than is true with regard to concentration in manufacturing industries.[99] It may be observed, however, that inasmuch as there are many villages in the country without food chains, the small percentage is an underestimation: it would rise if the total sales included only those in places where chain stores operate. Moreover, percentages of totals for the country are at times misleading. We saw in connection with the milk industry that, while the two leading distributors together controlled a very small percentage of the total, various large cities were subject to oligopolies. The same situation pertains to other products.[100] It is noteworthy, too, that in food retailing, as in retailing generally, the frequently meager pursed, inexperienced tradesman can hardly meet the chain store prices. Between the costs of the chain stores and the prices charged by the independents there is an area within which the chain store in given localities can exercise a degree of price policy. Stated otherwise, the product and price of the chain store do not encounter in the product and price of the independent a very close substitute. This remark also applies to Dr. Wilcox's and Dr. Hoffman's[101] stress on ease of entry: the inefficient small newcomer is hardly an effective competitive threat to the chain.

[100] *Competition and Monopoly in American Industry*, monog. no. 21, p. 111

[101] *Large-Scale Organization in the Food Industries*, monog. no. 35, p. 86.

One may demur as well to Dr. Hoffman's criterion of profits.[102] The profits of the five largest food chains have been unusually high—over 25 per cent on the investment (including long-term debts) in 1926, and declining to over 11 per cent in 1934-36. The full weight of Dr. Hoffman's contention falls on the consideration that, as the chains grew in percentage of the country's business, their rate of profit steadily declined. To him this fact suggests that "exorbitant chain-store profits must have some other explanation" than monopoly. There may be some other explanation, but the inevitability of the deduction may be questioned. One might suggest that under the pressure of investigations, public opinion, and antichain legislation the chains may have been induced to moderate the exploitation of their monopoly advantage. One would also have to be certain that there had been no overcapitalization, no profit concealment, and no change in other effective circumstances. The question relating to the degree of competition or monopoly in food chains awaits further study.

The drug trade. A careful statistical investigation is presented of retail prices in the drug trade, comprising drugs, toiletries and sundries.[103] In this sphere nonprice competition dominates the picture, and the consumer is so much in the dark about the utilities of the articles that a price considerably below the customary level arouses his suspicion regarding their quality. A chain store offered its own brand of aspirin at 19 cents for a hundred tablets whereas the prices of the best known brands varied from 59 to 75 cents. The public bought very little of the chain store product; but when the price was raised to 49 cents the volume of sales expanded greatly (p. 351). In this trade products identical in all essential regards command widely different prices, frequently out of all relation to cost of manufacture; and there are fluctuating deviations from the list prices among the stores. As is to be expected, small independent druggists in outlying districts charge higher prices for well-known advertised goods than large and conveniently located units.

The drug trade is preëminently subject to the resale price controls which have recently swept over the country, and there is impressive evidence that, but for the "fair trade" laws, the consumer would enjoy lower prices. After the Supreme Court decision in December 1936, upholding the constitutionality of resale price maintenance laws, many prices began to exhibit alike a narrower dispersion among stores and a higher average. Although many an independent drug store matches the prices of chain stores, the chain prices of nationally advertised merchandise commonly rank lower, even where price maintenance ap-

[102] *Ibid.*, p. 96.

[103] *Price Behavior and Business Policy,* monog. no. 1, Pt. 3.

plies, although after the appearance of price maintenance laws price cutting by chains diminished perceptibly. As one would expect, the price range of widely advertised brands exceeds the prices of less known private brands or of unbranded goods of the same quality, but the magnitude of the differentials is often striking indeed (pp. 369-71, 80). With the expansion of "fair trade" legislation some of the large distributors, like department stores in New York City, began to advertise the savings to the consumer purchasing private brands. There is also evidence, however, that some large units, content with the substantial margins of price-maintained products, lost the incentive to push their own brands.

Price-lines. There is finally an interesting account of an infrequently mentioned type of nonprice competition, price-lines.[104] In women's apparel, radios, vacuum cleaners, refrigerators and other goods, the quotations of different companies cluster about definite prices, sanctioned by custom, with arbitrary intervals in the series. Thus the prices of a certain type of girdle will run at $2.95, $2.98, $3.39, $3.50, $3.59, $3.95, and so on, with the greatest frequency of sales at $3.50 and $5.00. Sellers will quote the same prices, but will compete in style, material and workmanship. Some manufacturers of women's dresses will specialize as a $10.75 house or a $14.75 house. Even in a depression, unless there is a great shake-up, the price-lines hold firm, and better material and craftsmanship are put into the article; or else, when possible, the size is increased.

IV—Concluding Observations

As far as the T.N.E.C. investigations relate to price and production policy, it may be said that, aside from new data here and there and an occasionally interesting viewpoint and aside from the testimony by experts, especially on the construction and steel industries, the Hearings are verbose, repetitive, and descriptive; and that the monographs, while containing much fresh statistical exploration, are in the main bent on summary rather than analysis. The ratio of ore to metal is high.[105] None the less the cumulative effect of the panorama of problems presented on the numerous pages is bound to stimulate generalizations and questions which will doubtless vary with the reader. The present reader ventures the following observations.

One, the traditional belief that self-interest begets competition does

[104] *Ibid.*, pp. 70-75, 102-03, 242-51, 382-84.

[105] These remarks are far from predicting a career of limited usefulness for the T.N.E.C. publications. On the contrary, one may be confident that for years to come scholar and layman alike will turn to this rich storehouse of information, which bids fair to outrank the Report of the Industrial Commission.

not seem to accord with actuality. Self-interest seeks the maximization of revenue, and this often implies what Adam Smith called the monopolizing spirit. Competition is not the life of trade; and when circumstances permit monopoly advantage is sought even by the small manufacturer, the village store keeper, and the man in overalls. Monopoly is not the unique sin of big business; nor is it the peculiar attribute of modern days.

Two, competition does not always typify a smooth adjustment by rhythmic oscillations toward a beneficent equilibrium. The experience in agriculture, crude oil, and fluid milk seems to suggest that competition may be associated with disorder and distress. To avoid the pains of adjustment, there must be mobility of resources; that is, pure competition must also be perfect competition. Competition, however, postulates many sellers, and where many people are involved varieties of obstacles are likely to present themselves to their mobility. Thus competition is not apt to be perfect, and, instead of symbolizing ready adjustment, may offer painful economic (and political) problems before a transition has been made.

Three, various sectors of our economy exemplify the sort of monopolistic competition that offers the buyers good alternatives in price and quality and, accordingly, approximate competition closely enough for practical purposes so that an attempt to make the approximation closer, by social policy, may not be worth the effort.

Four, we need to explore more categories of markets. The classification of pure competition, product differentiation, and oligopoly is superior to the old dualism of competition and monopoly. Nevertheless, the diversity of market situations seems to demand a more extended classification and analysis of basic market patterns.

Five, with the dominance of advertising, salesmanship, and product differentiation generally, consumer utility becomes a concept more puzzling than before. Economics teaches that consumer utility governs the optimum allocation of resources, under competition. But when consumers' choices are largely governed by advertising producers, the maximization of utility assumes a new complexion, and the tenet that the consumer is the ultimate sovereign over the producer's moves may need revision. If we decide to accept consumer choices as primary economic data without regard to the antecedent utility calculations, the query arises as to what constitutes the aim of an economy, what it seeks to maximize, and what is the paramount criterion by which we can judge one economic system as against another. The concept of utility is pivotal and cannot be eliminated.

Six, the insistence on establishing competition in various sections of our economy may often face a dilemma. If the advantages of large size

are to be achieved, many industries will be dominated by small numbers. If the industry is atomized into many firms, the result may be the inefficiency of small size compounded with the possible disorder of competition, if the product is homogeneous. If the product is differentiated, the presence of many firms may symbolize overinvestment, undercapacity, and a high price although without a monopoly profit.

Seven, we need to reformulate our attitude to public policy with regard to price and production. The nineteenth century accepted *laissez-faire*. In the first quarter of the present century many seemed to be content with the antitrust laws, if properly enforced. Then came the new formulations of the theory of competition and monopoly. Where do we stand now?

Lawrence College

SAVINGS AND INVESTMENT: PROFITS *VS.* PROSPERITY?

By MOSES ABRAMOVITZ

Introduction

The investigations of the Temporary National Economic Committee are a momentous work. They are the product of a mood of deep despair over both the justice and the efficiency of our economic arrangements. The information compiled in the Hearings and monographs, though much of it is neither new nor even improved, is a telling indictment in its general effect. There can be little doubt that, in the hands of a powerful party representing the interests of workers and farmers, this official portrait of our economy would be a powerful, perhaps decisive, political instrument of reform. Even in the confused political organization of this country it would not, in times of peace, have been without effect. It is clear, however, that the committee completed its work at a time when the country is particularly unready to use it. In the circumstances, it is perhaps not merely excusable but even desirable to treat it, not as the political document which it was meant to be, but as a set of academic materials, to ask what information it contributes to our knowledge of the economy, what general policies seem implicit in the analysis of the monographs and the testimony of the witnesses, and how well these policies fit the problems of the economy as these are now best conceived.

The particular aspects of these problems to which this essay directs itself are those especially connected with our current processes of saving and investment. And on these points, as no doubt on others, it is not an easy job considered from the point of view of scientific advance to reap the fruits of all the labor. Witnesses naturally considered their function to be that of elucidating the simpler facts in the simplest style. Analysis is often distorted to avoid difficulty. Suggestions of policy are left implicit to avoid prejudicing the authority of factual testimony. While the authors of the monographs felt somewhat freer to deal with the complexities of their subjects, their status in the civil service enjoined a still more cautious approach to policy. The final recommendations of the committee are hardly consistent with the scope of the testimony taken or the problems raised.

All this is, no doubt, inherent in the political process of which these materials are a by-product. From the point of view of their contributions to our knowledge, a narrow review of what was said and written, of what should have been treated but was not, would be not only ex-

hausting but also unprofitable. It is better to emphasize the contributions and forget about the failings.

From this point of view some organization is necessary. The most convenient standpoint from which to take departure is the Keynesian convention: Income = Consumption + Investment. Our problems then are: What factors determine the levels of consumption and investment? These problems are broad enough to include all that is relevant in our materials and are, in fact, the point of view from which the relevant monographs and testimony proceed. The character of our materials also makes it convenient to divide the factors bearing on investment into two classes, those dealing with the "rate of interest" (for which we ought to read: "all matters affecting the cost of financing"), and all other conditions determining the attractiveness of investment.

One further bit of cross-classification seems necessary. Our interest runs toward two aspects of national income, its level and its fluctuations. We wish to raise the level and to increase its stability. We would not wish to accomplish our desires in one direction at too great a cost in the other. And, of course, these two aspects of national income are intimately connected causally. In particular, the risks attendant on instability tend to reduce the general attractiveness of investment and thus the general level of national income. Thus, attempts to attain a higher level of income at the expense of stability may defeat their own purpose; and, contrariwise, measures which promote stability and do not directly prejudice the level of income are likely to act to raise it because they reduce the risks attendant on investment.

From an analytical standpoint, moreover, there is a strong tendency —too often exemplified in the T.N.E.C. materials—to infer the characteristics attendant upon certain long-run levels of income from data inherently cyclical in character. One cannot judge with any accuracy how much more people tend to save or invest during a decade when the national income stands at an average level of 87 billion dollars than when it stands at 43 billion dollars by comparing 1929 with 1932. All these considerations urge the necessity of keeping the two problems in mind, both in their divergences and in their parallelisms. Throughout the essay, therefore, we shall ask what the conditions under review portend not only for the level of activity but also for its stability.

I. The Relation between Income and Savings

From the point of view of maintaining a national income of satisfactory size, studies must ask: how much will the community desire to save when the national income is high? The critical statistic is the average propensity to consume. From the point of view of the stability

of income, one wants to know how sensitive is expenditure to a change in income. The question is: How much less will people spend if their income falls by a dollar? The critical statistic is the marginal propensity to consume. These two characteristics of the relation between income and savings are fundamentally distinct and independent.

A community which is able to obtain a high income because its desire to spend at such a level of income is very strong is not necessarily an economy which will resist the impact of forces making for reduced income flows. If the community tends to save but a small amount, but to cling tenaciously to that volume of savings, its rate of expenditure will in fact be very sensitive to reductions in income. It is essential, therefore, to deal with the two problems separately.

1. *The Level of Income and the Level of Savings*

Our interest centers in two questions: How much is the community likely to try to save at high levels of income; and why does it try to save so much? The first question was of major concern to Professor Hansen[1] and to Dr. Currie[2] in their testimony and to Dr. Altman[3] in his monograph. All these witnesses used Dr. Kuznets's well-known estimates of national income and capital formation as the basis of their observations. The witnesses were naturally at a disadvantage for lack of data running over more than the last two decades, years marked by an unparalleled depression which carried income down to levels involving negative saving. For lack of better materials, recourse was had to annual comparisons and conclusions were necessarily limited to pointing out the general order of magnitude of savings associated with levels of national income which furnished "reasonably full" employment. Thus, Professor Hansen used an average of the years 1923-29[4] and Dr. Currie, an average of the years 1923-28[5] to indicate the level of savings associated with high prosperity. In the period, gross savings amounted to about 19 per cent of gross national income. While the witnesses ventured no definite predictions, they thought it worth while to hold out this ratio as a useful basis for calculating the rate of saving likely to accompany satisfactorily high levels of nationl income in the future.

The witnesses make it clear, however, that factors other than the size

[1] *Investigation of Concentration of Economic Power,* Hearings before the Temporary National Economic Committee; 76th Cong., 1st sess., May, 1939, on Pub. Res. 113 (75th Cong.). Pt. 9, *Savings and Investment* (Washington, Supt. Docs., 1940), pp. 3500 *ff.*

[2] *Ibid.,* pp. 3536 *ff.*

[3] O. L. Altman, *Saving, Investment, and National Income,* T.N.E.C. monog. no. 37 (Washington, Supt. Docs., 1941).

[4] Hearings, Pt. 9, *Savings and Investment,* p. 3498.

[5] *Ibid.,* p. 3537.

of the national income have an important bearing on the rate of saving. Indeed, it is these other factors which provide the community with its opportunity for control. Without developing their analysis systematically, they nevertheless point out that our communal propensity to save is likely to vary directly with the degree of inequality in the distribution of income, the amount of profits earned by business, and the percentage of such profits retained by enterprises, and, inversely, with the size of capital gains, the weight of taxation, and the degree to which taxes are borne by the relatively rich.

Oscar Altman[6] uses the familiar materials of the National Resources Committee study, *Consumer Expenditures in the United States 1935-36*, to emphasize the importance of inequality in income distribution. The showing of the committee's data on the relation between the income and savings of American consumers at various income levels is striking. In the year studied it appears that the 59 per cent of our families earning less than $1,250 spent more than they earned while the 2.3 per cent of our families earning over $5,000 saved 79 per cent of the 6 billion dollars saved in that year by individuals. Families having incomes between $5,000 and $10,000 saved, on the average, 30 per cent of their income. But families earning over $20,000, who were less than .3 per cent of all families, saved 50 per cent of their income and accounted for nearly 40 per cent of the total saved by individuals. The average income of all families in the same year was almost exactly $1,500. A rough estimate of the saving which would have been done by individuals if all families had received this average income is 1.8 billion dollars.[7] The actual saving apparently effected came to 5.9 billion dollars.

Adolph J. Goldenthal[8] attempted to estimate the aggregate income earned by the most fortunate one per cent of income receivers. His figures included capital gains and losses in income. But a rearrangement of his data by Dr. Altman[9] provides us with figures excluding capital gains and reveals that the highest one per cent of income recipients received 13 per cent of total individual incomes on the average during the years 1918-37. Moreover, the percentage of income earned by this highest income bracket was remarkably stable, varying between 11.6 per cent in 1920 and 14.3 per cent in 1928.[10]

[6] *Saving, Investment, and National Income,* monog. no. 37, pp. 16-17.

[7] Calculated by the present writer by applying to the total income of all families, as determined by the Consumer Expenditure Study, the average percentage of income saved by the two income groups, $1,250-$1,500 and $1,500-$1,750.

[8] *Concentration and Composition of Individual Incomes, 1918-1937,* monog. no. 4.

[9] *Saving, Investment, and National Income,* monog. no. 37, p. 18.

[10] These percentages are probably an underestimate of the share of the highest one per cent of income receivers. Mr. Goldenthal was unable to estimate the total income received by individuals with the highest economic incomes. His dependence upon Treasury materials

Mr. Goldenthal also presents extremely interesting information on the sources of inequality in the distribution of incomes. He finds that, while compensation for personal services accounted for 83 per cent of all income received by individuals, and income from property for but 17 per cent during the years 1931 to 1935, the highest one per cent of all income receivers secured 49 per cent of their income because of their ownership of property and earned only 51 per cent by "personal service,"[11] a category which is taken to include the total earnings of the owners of unincorporated concerns. Thirty-seven per cent of all income from property during these years went to the highest one per cent of income receivers. Of greatest importance in accounting for the property income of this richest group is its dividend roll. Some 60 per cent of all its income from property came to this topmost income bracket in the form of corporate dividends; and this group received an even higher proportion of all dividends than of property income as a whole: 63 per cent against 37 per cent.

Dividends then play a notable part in giving the members of our highest income bracket the disproportionate share of our total income which they receive. But dividends are even more important in accounting for differences of income within this sparsely populated region. Martin Taitel[12] provides the figures for all federal income taxpayers, as shown in Table I.

---

forced him instead to estimate the total incomes of the one per cent of income receivers who obtained the highest *statutory net* incomes. Statutory net income differs from a more relevant definition of income by including capital gains and losses and by excluding contributions, certain taxes paid, tax exempt interest on government securities, and certain other minor items. Hence, it is clear, as Mr. Goldenthal points out, that "the proportion of total economic income received by individuals with the highest statutory net incomes would obviously be somewhat less than the proportion of total economic income received by those with the highest economic income."

[11] The years 1932 and 1933 are omitted from the data. Capital gains were excluded from total income and income from property by the present writer. Savings of individual entrepreneurs and of partnerships not withdrawn from their businesses are included by Mr. Goldenthal in individual incomes. The figures presented in the text are based on Table 10, p. 37, and Table 12, p. 39, of Mr. Goldenthal's monograph (no. 4, *Concentration and Composition of Individual Incomes, 1918-1937*).

A possible distortion of the shares of total income accounted for by personal services and property respectively in different income brackets may possibly inhere in the fact that, in Mr. Goldenthal's classification, entrepreneurial incomes are considered to be a return to personal services alone. It seems unlikely, however, that this can be of great importance. Figures presented by Mr. Goldenthal (*ibid.*, p. 48) make it clear that entrepreneurial incomes accounted for less than 20 per cent of total income for both income recipients earning more than $5,000 and those earning less than $5,000 and that the shares of total income accounted for by entrepreneurial earnings in the two groups did not differ by more than two percentage points in any of the four years, 1926, 1929, 1932 and 1935, for which data are presented. Moreover, only part of the total earnings of entrepreneurs can be attributed to their capital investments.

[12] *Profits, Productive Activities and New Investment*, monog. no. 12, p. 53.

Perhaps the most significant information in the table appears in the last column. These data indicate that even at the lower levels of taxpayers' incomes, substantial portions of the difference between the average incomes of successively higher brackets are due to differences in the amount of dividends received. Above the $50,000 level over one-half of the difference is attributable to dividends, and this ratio becomes even higher as incomes rise. Figures for 1932 and 1929 exhibited similar characteristics.

TABLE I—APPROXIMATE RELATION BETWEEN GROSS INCOME AND DIVIDEND RECEIPTS: 1936

Average gross income	Dividend receipts		Difference between successive average gross incomes	
	Approximate average	Percentage of gross income	Amount	Percentage accounted for by dividend receipts
$ 2,400	$ 125	5.2	—	—
5,000	551	11.0	$ 2,589	16.5
10,000	1,825	18.3	5,000	25.5
25,000	7,843	31.4	15,000	40.1
50,000	20,306	40.6	25,000	49.9
100,000	49,402	49.4	50,000	58.2
150,000	79,997	53.3	50,000	61.2
300,000	181,984	60.7	150,000	68.0
500,000	328,915	65.8	200,000	73.5
1,000,000	704,117	70.4	500,000	75.0

The rich, however, are not rich because of the direct yield of their property alone. As much of their income comes to them in the form of salaries and fees (31 per cent) as comes in the form of dividends (30 per cent).[13] In 1929, when the average income receiver earned about $1,150 in the form of wages and salaries, the comparable figure for the highest one per cent of our income receivers was $6,859. In 1931 the comparable figures were $864 and $6,130. One would, however, be ingenuous indeed, if one thought of the "earned" income of the rich as substantially independent of their property income. The "pickings" as well as the profits of property are great. The relatively small group of men who receive the highest property incomes also control our corporations. When corporations make profits and furnish these men dividends, they also furnish a fund which makes possible the compensation of executives at high salaries, the payment of bonuses and the like. Indeed, the same thing is probably true if the corporations are merely

[13] The figures apply to the average of the years 1919-35, 1932 and 1933 being excluded. The calculations are based on *Concentration and Composition of Individual Incomes*, monog. no. 4, Tables 10 and 12.

big, even if unprofitable. Big and, more especially, profitable corporations can afford to pay extremely high fees for the services of fashionable and, no doubt, somewhat more skilled attorneys, accountants, and consulting engineers. Rich individuals can afford to pay their attorneys and physicians in the same liberal fashion. Finally, one may add that property income means the education and, even more, the connection and entrée which qualify individuals for the more lucrative positions in the economy. All this, of course, is not meant to belittle the real importance of sheer ability.

It is clear that the magnitude of property earnings, more especially of profits, is a critical determinant of the volume of individual savings. Profits, however, affect the savings of the community at still another point. When business makes profits it usually retains part of these net earnings either to finance its own purchases of capital goods or to increase its liquid assets. Dr. Altman used the Department of Commerce estimates of gross savings by nonfinancial enterprises and Dr. Kuznets's estimates of gross capital formation to indicate that, in two periods of relatively high income and high savings, 1925-29 and 1935-39, gross savings of business averaged 36 per cent and 35 per cent, respectively, of aggregate gross capital formation.[14]

Dr. Kuznets's recently published study of national income provides us with a convenient gauge of the importance of the net savings of business.[15] During the prosperous period 1919-28, incorporated and unincorporated business together accounted for more than 19 per cent of the net savings of the community. In the highly prosperous year 1929, the figure was 26 per cent. In the relatively depressed period, 1929-38, when corporate net earnings alone dropped to an average of 2.3 billion dollars a year from 4.9 billions in the earlier period, business enterprises dissaved at the rate of 2.3 billion dollars a year. Even in the relatively prosperous year 1937, when the community saved 6.4 billion dollars, business enterprises dissaved one billion dollars.

It is not easy from these figures to arrive at any definite impression of how important business savings are likely to be during the years of high prosperity. The latter twenties were quite exceptionally profitable years; even the payment of unprecedentedly high dividends did not prevent corporations from adding substantial amounts to surplus. The thirties, on the other hand, included the country's deepest depression. Moreover, when recovery came, profits failed to rise to anything like pre-depression levels. In 1937, the best of these years, net profits of corporations before taxes were not higher than in 1922 when our na-

[14] *Saving, Investment, and National Income,* monog. no. 37, p. 15.

[15] *National Income and Its Composition 1919-1938* (New York, Nat. Bur. of Econ. Research, 1941), Table 39, p. 276.

tional income was some 14 per cent smaller.[16] In addition, the short-lived but effective federal undistributed profits tax[17] probably forced the distribution of a considerable volume of corporate dividends which would otherwise have been retained. On balance, therefore, it seems a fair guess that future boom periods will see substantial savings by business enterprises, perhaps of the order of magnitude which characterized the twenties.

There is some question, however, about the accuracy with which the depreciation and depletion allowances actually charged by business truly measure the investments required to maintain capital intact. Professor Hansen[18] argues that a much smaller amount of replacement expenditures than the amounts actually charged to depreciation may be sufficient to maintain the productivity of the total capital stock. If this were so, the effective net savings of business required to be absorbed by investment intended to expand output would be considerably larger than the figures cited in the text above.

In support of his views Professor Hansen cites the fact that depreciation allowances are, in the ordinary course, used to provide improved machinery operated by more efficient techniques. Against this view one might stress the importance of the obsolescence which accompanies technological advance. The difficulty at bottom is a conceptual one. A useful definition of the amount of investment required to maintain capital intact may be quite different in an analysis of money flows and in other conceivable problems. One way out of these conceptual difficulties is to conceive of the savings-investment problem in gross terms alone. On this basis, of course, the importance of business savings is unquestionable.

Still another unresolved problem connected with business savings concerns the net reduction in the communal propensity to consume which might be effected by forcing a larger distribution of business profits. Although great stress was laid in both the testimony and monographs[19] upon the extent to which retention of earnings of business added to the savings of the community, no attempts were made to indicate what the net effect upon the community's saving was likely to be if earnings were distributed in greater volume.

The logic of the situation is, of course, such as to leave no doubt that,

[16] *Ibid.*, Table 37, p. 269.

[17] Some notion of the effect of the undistributed profits tax on the net savings of corporations may be gleaned from the fact that corporations dissaved 700 million dollars more in 1937 than in 1938 when the tax was reduced to nominal levels, although corporate profits fell from 3.5 billion dollars in 1937 to 2.8 billion dollars in 1938. *Ibid.*, table 22, p. 216.

[18] Hearings, Pt. 9, *Savings and Investment*, p. 3510.

[19] See especially the testimony of Oscar Altman, *ibid.*, pp. 3669-3702,

other things being equal, a reduction in business savings is likely to reduce the total savings of the community. The individuals to whom the profits of business are distributed are unlikely to save anything like the entire amount. This would be true even though the very rich secure most of the profits distributed. Still, a quantitative expression of the probable net reduction in savings is vital; for it is clear that if business is forced in somewhat greater measure to finance itself *via* the security markets, this constitutes some bar to investment. Unless the reduction of savings is greater than the probable reduction of investment, a more liberal distribution of profits would be of no benefit.

Paul Samuelson's study of this problem led him to estimate that a reduction of business savings of $1.00 was likely to cause individuals to increase their savings by about 20 cents.[20]

TABLE II—NATIONAL INCOME AND SAVINGS, 1919–28, 1929–38[a]

(All figures in billions of 1929 dollars)

Classification	Annual average	
	1919–28	1929–38
National income	68.6	71.1
Aggregate payments to individuals, excluding entrepreneurial savings	65.4	74.3
Savings by individuals	3.4	4.8
Savings by business	2.3	−3.2
Total private savings	5.7	1.6

[a] From *National Income 1919–1938* by Simon Kuznets, Occasional paper no. 2, National Bureau of Economic Research.

Somewhat less formal use of national income figures yields much the same impression. The figures below are abstracted from a recent paper by Simon Kuznets.

Although the national income in constant dollars was larger in the second decade than it was in the first, savings of individuals and business together were much smaller. The entire decline in savings is accounted for by the dissaving of business. A reduction of business savings of 6.4 billion dollars was accompanied by a reduction of total private savings of nearly as much (5 billion dollars). This occurred in spite of the fact that individual savings undoubtedly increased between the first decade and the second for reasons other than the decline in business savings. Although the share of income going to the richest

[20] See his note in Professor Hansen's *Fiscal Policy and Business Cycles*, pp. 250-60. Dr. Samuelson is skeptical about the value of these figures because of the high correlation between business savings and aggregate income payments to individuals.

section of the population was about the same in both decades,[21] aggregate income payments to individuals increased by about 14 per cent. Capital gains, which probably induce individuals to spend a larger proportion of their incomes than they otherwise would, fell from an annual average figure of 1,700 million dollars in the first decade to only 81 million dollars in the second decade, a comparison which probably greatly understates the decline.[22] The comparison, in sum, constitutes a rather telling bit of evidence in favor of the notion that a decline of business savings is likely to lead to a rather large comparative decline in total savings, other things being equal.

The last important component of savings is that done by governments. Dr. Altman indicates that during the prosperous period, 1925-29, governments accounted for 10 per cent of gross savings. On a net basis the share of governments' savings is considerably larger—22 per cent.[23] These figures emphasize the margin of control largely at the discretion of governments. Prosperous years in the future need not be characterized by such a large volume of investment as has marked them in the past, provided that a more enlightened control of fiscal policy prevails.

While inequality in the distribution of income is perhaps the most important cause of one great volume of individual savings, the distribution of income is particularly subject to modification through the medium of taxation. From this point of view, the character of our tax

[21] After deduction of federal income taxes, income receivers falling in the highest one per cent of the income distribution apparently obtained 12.2 per cent of all income received in the decade 1919-28. In the second decade the same group obtained 12.6 per cent of all income received by individuals.

The figures for this computation were derived in the following manner:

1. Income payments excluding capital gains but before income taxes, from S. Kuznets, *National Income 1919-1938* (Occasional paper no. 2, Nat. Bur. Econ. Research), Table 1, p. 7.

2. Incomes of the highest one per cent including capital gains and before taxes, from *Concentration and Composition of Individual Incomes,* monog. no. 4, Table 12, p. 39.

3. Capital gains of the highest one per cent, *loc. cit.,* except 1937, which was estimated by the present writer by applying the ratio of capital gains realized by the highest one per cent in 1936 to total capital gains in 1936 to Mr. Goldenthal's estimate of total capital gains in 1937. (*Ibid.,* Table 10, p. 37.)

4. Federal income taxes paid *in toto* and by the highest one per cent, *ibid.,* Table A-6, p. 98.

Inability to estimate the realized capital gains of individuals in 1931, 1932, and 1938 made it necessary to exclude these years from the second decade.

[22] The figures are computed from *Concentration and Composition of Individual Incomes,* monograph No. 4, Table 10, p. 37. The average for the second decade does not include the years 1931 and 1932, when it seems likely that capital losses were large, and 1938, when the capital gains, if any, were probably small. Changes in the income tax law make the figures for 1935, 1936, and 1937 understate the amount of capital gains to some degree, a fact which counterbalances to some extent the effect of the years omitted.

[23] Kuznets, *National Income and Its Composition,* Table 39, p. 276.

system is a critical determinant of our tendency to save. This is the subject of a particularly bold and suggestive monograph by Gerhard Colm and Helen Tarasov.[24] Working on a problem for which the materials are poor even as economic data go, the authors were yet courageous enough to attempt to approximate answers to relevant questions and not merely to those questions to which relatively accurate answers could be made. They attempt, in fact, to trace as accurately as poor material and the nature of the problem allow the incidence of all federal, state and local taxation upon the members of the various income size groups for the fiscal year 1939.

A preliminary allocation of taxes into two groups—those which are directly levied on consumption or may be presumed to be shifted to consumers, and those personal taxes which may be presumed to be paid by persons on whom they are levied—yields the highly interesting estimate that over 70 per cent of the total tax revenue in 1938-39 fell on consumption, while only 30 per cent took the form of personal levies which could not be shifted to others.[25] State and local taxation are, as is well known, more culpable in this respect than federal taxation, and it appears from Dr. Colm and Miss Tarasov's figures that over 85 per cent of state and local taxes are finally borne by consumers.

With all the caution required by their problem,[26] the authors present the following figures on the percentage which taxes are of income for various income groups.

It is apparent that whatever elements of progression existed in our pre-war tax system were found in the federal tax system alone, and even federal taxes only begin to be seriously progressive above the $10,000 income level. From the point of view of distributive justice, the reform of the American tax system still has far to go. It is clear, too, that progress in this direction will involve substantial inroads upon the volume of savings. Although Dr. Colm and Miss Tarasov do not venture estimates of the effect of an increase in the progressiveness of our tax system upon the volume of saving, their material was clearly organized to be relevant to that problem. This question will be discussed at some length in a later section of this paper.

[24] *Who Pays the Taxes?* monog. no. 3.

[25] This calculation is based on figures pieced together from various tables of *Who Pays the Taxes?* monog. no. 3. Following Dr. Colm and Miss Tarasov, taxes which are presumed to fall on consumers include employers' contributions to social security taxes, though these may well fall on labor, and taxes on all real estate improvements. Corporation income, excess profits, and stock taxes are assumed to fall on the income or equity of corporate shareholders and are, therefore, included among the nonshiftable personal taxes.

[26] It seemed impossible in a paper of this character even to begin to summarize the difficulties of estimation encountered by the authors in arriving at their final tables. Interested readers are referred to Dr. Colm and Miss Tarasov's own concise presentation.

From this review of the determinants of saving, the magnitude of profits emerges as of critical importance. When profits are large, business retains a substantial part of its net earnings, and these retained net earnings constitute a considerable part of all our savings. The dividends which business pays go in great part to the rich and form a substantial portion of their total income. And since the rich tend to save a very large portion of their incomes, dividends account for a much larger percentage of the community's savings than they do of the community's income. Finally, profits probably are the basis of a considerable portion of the nondividend receipts of the rich. By providing a surplus fund at the discretion of business directors, profits make possible the payment of extremely high salaries and bonuses to corporate officials and fees to the accountants, attorneys, and engineers who serve big business. As the source of a large part of the personal incomes of the rich, profits play the same rôle in making possible the incomes of the better paid physicians, attorneys and architects who serve rich individuals.

TABLE III—TAXES AS A PERCENTAGE OF CONSUMER INCOME: 1938–39

Income classes	Taxes as percentage of income			Savings as percentage of income
	Federal	State and local	Total	
I Under $ 500	7.9	14.0	21.9	−24.3
II $ 500– 1,000	6.6	11.4	18.0	− 2.0
III 1,000– 1,500	6.4	10.9	17.3	5.2
IV 1,500– 2,000	6.6	11.2	17.8	5.8
V 2,000– 3,000	6.4	11.1	17.5	9.6
VI 3,000– 5,000	7.0	10.6	17.6	16.8
VII 5,000–10,000	8.4	9.5	17.9	28.4
VIII 10,000–15,000	14.9	10.6	25.5	32.3
IX 15,000–20,000	19.8	11.9	31.7	32.3
X 20,000 and over	27.2	10.6	37.8	38.3
Total	9.2	11.0	20.2	11.4

Martin Taitel provides us with figures which allow us to secure some summary impression of the importance of profits in accounting for communal savings. He estimates, for a number of years between 1920 and 1937, the amount of savings effected out of corporate dividends by dividend receivers with incomes of more than five thousand 1935-36 dollars. His method involves the distribution of dividend payments by the income levels of the recipients and the use of the National Resources Committee 1935-36 estimates of the percentages of income saved at various income levels to estimate the amounts of dividends

saved.[27] Since savings out of dividends received by individuals with incomes of less than $5,000 were neglected, there can be little doubt that Mr. Taitel's figures do not exaggerate savings from this source. To these estimates we have only to add the sums saved by incorporated and unincorporated business to secure estimates of total savings from profits. For this purpose the present writer has utilized Dr. Kuznets's recent estimates of these magnitudes.[28]

Table IV presents estimates of savings from profits for four prosperous years, together with related information.

TABLE IV—ESTIMATES OF PROFITS AND OF SAVINGS FROM PROFITS

(In billions of dollars)

Classification	1925	1929	1936	1937
1. Savings from dividends[a]	1.4	2.0	1.1	1.2
2. Retained earnings of corporations[b]	0.8	1.5	−0.7	−1.4
3. Entrepreneurial savings[b]	1.6	1.1	1.2	0.4
4. Total savings from profits (Lines 1+2+3)	3.8	4.6	1.6	0.2
5. Total savings[b]	9.3	10.0	5.4	6.4
6. Percentage: savings from profits divided by total savings	41.0	46.0	29.6	3.1
7. Dividends[c]	4.4	6.3	4.8	4.9
8. Total "profits" (Lines 2+3+7)	6.8	8.9	5.3	3.9
9. National income[d]	76.0	87.2	62.9	70.5
10. Percentage: total profits divided by national income	8.9	10.2	8.4	5.5

[a] *Profits, Productive Activities and New Investment*, monog. no. 12, Table 14, p. 63.
[b] Kuznets, *National Income and Its Composition 1919–1938*, Table 39, p. 276.
[c] *Ibid.*, Table 70, p. 348.
[d] *Ibid.* Table 1, p. 137.

The figures above provide a striking illustration of the importance of profits in accounting for savings. Although profits form no more than 10 per cent of the national income in any of the years shown, they were apparently responsible for as much as 46 per cent of our total savings.[29] In 1937 the reverse is true, but the circumstances serve to emphasize the importance of the magnitude of profits in accounting for savings. In

[27] See *Profits, Productive Activities and New Investment*, monog. no. 12, chap. 6, sec. C, and chap. 7 for a detailed description of Mr. Taitel's methods.

[28] Mr. Taitel's own estimates of retained earnings were discarded because they were not adjusted to eliminate revaluations of assets.

[29] The estimates of total profits shown in Table IV possibly underestimate somewhat the magnitude which is relevant to our problem. Our estimate includes corporate dividends and the retained earnings of incorporated and unincorporated business. It does not include that part of entrepreneurial withdrawals which are properly profits. Consequently, our comparison of the difference between the proportion of national income and the proportion of savings accounted for by profits somewhat overstates the case.

that year, corporations maintained their dividends at the 1936 level although their profits fell by 15 per cent. The same condition must have been true of unincorporated business, judging from the reduction in entrepreneurial savings. As a result, business as a whole dissaved one billion dollars and savings from dividends failed to make up for this high rate of business dissaving.

The moral may be underscored by noting that, when profits change, a very large proportion of the change is likely to go into or come out of savings. If we total, without regard to sign, the three changes in profits between the four years shown in Table IV, we find that the sum, 7.1 billion dollars, is associated with changes in savings from profits which total 4.2 billion dollars. The associated changes in total savings were only 6.3 billion dollars.

All this is information of great interest. But its bearing upon our problem is less close than may at first appear. We are interested in estimating how much investment is likely to be necessary in order to *maintain* income at a high level. The figures we have reviewed tell us how large was the volume of savings when income stood temporarily at a cyclical peak. For various reasons the amount saved out of a given income produced at a cyclical peak is likely to be quite different from the amount the community is likely to save from the same income if this national dividend can be sustained for some time.

One important factor probably operates to make the propensity to save smaller at cyclical peaks than in the long run. During a business boom capital gains are apt to be large and to encourage people to spend more from a given income than they would otherwise be inclined to do. Another factor working in the same direction is the use of consumer credit. While their incomes are increasing people are inclined to add to their present consumption by anticipating future income. But if income is stabilized, the volume of consumer credit outstanding may also be expected to stop rising, other things being equal.

Other possibly more important factors work in the opposite direction. They serve to indicate that the savings associated with high incomes, if the latter are maintained, will be smaller than is suggested by the figures we have reviewed. It seems plausible to suppose that consumption standards lag behind income. It takes time for people of given earnings to discover the opportunities which larger incomes afford, time to rearrange their situations to make full use of these opportunities, and time for the conventions of the group to impose their sway upon the recalcitrant. But possibly more important than any of these considerations is the fact that the profits earned in the production of a high level of income are likely to become smaller the longer that level of income is maintained. Profits are high at cyclical peaks in good part

because a high level of income has been reached only a short time after the community had known a low level. Except in cases where competition is virtually absent and entrance to an industry barred, the rivalry of existing firms and the entrance of new firms should lead to sufficient plant expansions to cause a substantial reduction in the volume of profits. Moreover, of the profits which are earned, business is less likely to retain so large a fraction since the urgency to provide reserves for a coming depression is reduced.

One can only speculate about the relative importance of these factors and about the possibility that other factors equally cogent have been overlooked. It is clear, however, that we know little as yet about the volume of investment required to maintain a given level of national income.

2. *Changes in Income and Changes in Savings*

Although the work here under review is based upon statistical materials which represent observations of a period marked by violent cyclical changes and although the data used were reported at relatively frequent intervals (annually), attention was almost entirely directed to the level of savings associated with high income. Beyond cursory remarks about the possibility that savings are likely to increase more rapidly than income as the country emerges from a deep depression,[30] no attention was given to the sensitivity of savings to changes in income. Material of the sort we have reviewed, however, is able to cast some light upon this problem.

For example, Rollin Bennett,[31] working with Harold Barger's quarterly estimates of income and consumption in constant prices for the years 1921 to 1938, found that a $1.00 increase of income was accompanied on the average by an increase of savings of approximately 37 cents. Paul Samuelson[32] presented estimates of the same sort based upon annual data in constant prices adjusted for changes in population. He found that a $1.00 increase of national income was accompanied by increased savings of 46 cents on the average.

[30] Compare the testimony of Lauchlin Currie, Hearings, Pt. 9, *Savings and Investment,* p. 3537.

[31] "The Significance of International Transactions in the National Income," *Studies in Income and Wealth,* Vol. 4 (New York, Nat. Bur. of Econ. Research, 1941). Mr. Barger's estimates on which these calculations were based will appear in a forthcoming publication of the National Bureau of Economic Research. Believing that the corporate profits which influence consumer expenditures are probably profits as reported rather than as adjusted for capital gains, Mr. Bennett used income figures before revaluation of assets.

[32] See, Hansen, *op. cit.,* p. 253. Dr. Samuelson used Dr. Kuznets's data as presented in *National Income and Capital Formation,* from 1921 to 1935 and estimates of the National Resources Planning Board from 1936 to 1939.

These results indicate a very high degree of sensitivity of savings to changes in income. Conversely, they indicate that, so far as our savings habits go, the forces making for stability of income are very strong.[33] This source of resistance to cyclical fluctuations, however, appears to depend to a much greater extent upon the reaction of business savings to a change in national income than upon the responses of individuals.

The present writer has estimated that business savings accounted for 38 per cent of the changes in net savings between peaks and troughs and troughs and peaks of business cycles between 1919 and 1938, while private savings accounted for but 26 per cent. The balance of the changes in savings was due to the action of governments.[34] The difference in the sensitivity of these various components of savings to changes in national income is emphasized by the fact that the average annual savings of business over the period as a whole was virtually zero while individuals saved, on the average, 4.2 billion dollars a year and governments about 700 million dollars.

Paul Samuelson[35] has attempted a more elaborate estimate of the same magnitudes with even more striking results. He studied the relation between consumption and aggregate income payments to individuals by years between 1921 and 1935[36] and found that, on the average, virtually the whole of every dollar of incremental income tended to be spent. The entire increase of savings associated with increases of income tended to take the form of business or governmental savings. The relation between total business savings and the national income produced yielded an extremely high marginal propensity to save—49 cents out of every $1.00 increase of income.

Dr. Samuelson considered that some part of the high degree of sensitivity of individual consumption to increases of individual income was due to business savings. Individuals may fail to increase their savings in part because business does it for them. He therefore attempted to discover the relation between consumption and aggregate income payments to individuals after allowing for changes in business savings. His results, presented with great diffidence because of the high degree

[33] The results of still other estimates of the propensity to save in the United States are summarized in Colin Clark's *The Conditions of Economic Progress*. Four different methods yielded results ranging from 30 to 33 cents of savings with each dollar of income increase, figures somewhat lower than those cited in the text.

[34] These figures are based upon Dr. Kuznets's estimates of savings as presented in *National Income and Its Composition 1919-1938*, Table 39, p. 276. The reference dates of the National Bureau of Economic Research were used to mark peaks and troughs of business cycles.

[35] See Hansen, *op. cit.*, pp. 255 *ff*.

[36] Again Dr. Samuelson's figures were drawn from S. Kuznets, *National Income and Capital Formation*. They are corrected for changes in the cost of living and in population.

of intercorrelation among the factors, indicated that if business savings did not vary from their level in 1929, individuals would raise their savings by about 19 cents when their incomes increased by $1.00. An increase of enterprise savings of $1.00 increases consumption by 23 cents.[37]

If these calculations are anywhere near the mark, then it would appear that a large part of such resistance to cyclical changes as is found in our economy consists in the fluctuation of business savings. The real objection to undistributed profits taxation may be found less in the fact that it constitutes a hindrance to the financing of small business than in the fact that it would tend to increase the violence of cyclical fluctuations.

II. The Inducement to Investment

The factors which determine the volume of investment can be grouped into two classes: those bearing on the profitability of investment, and those influencing the costs of securing the necessary resources. This section will deal with the first of these groups.

The testimony of Professor Hansen and Dr. Currie included statistical material and analysis relevant to the problem of stimulating a greater rate of investment.[38] Dr. Altman's monograph bore in part on the same question. Our review of the materials and analyses they offered properly starts with a statement of the country's position as they saw it at the time they testified and wrote.

Our recent record in the production of national income, they pointed out, has not been as good as it was in the past. Whether we calculate national income upon a net basis or a gross basis, in current values or in constant values, its level in 1937—the most recent pre-war peak year—fell short of its level in 1929. Since our population was larger in 1937 than in 1929, the drop in income per capita was even greater. Moreover, unemployment was probably far more serious in 1937 than in 1929 though here, of course, statistics are notoriously poor.

This decline in national income was associated with, and in a significant sense no doubt caused by, a far larger decline in the rate of capital formation. While net national income in 1929 prices dropped 7.2 per cent between 1929 and 1937, net capital formation declined

[37] Presumably the circumstances under which a hypothetical reduction of business savings occurs would have some bearing upon the results. A decline of business savings which reflects a reduction of profits and implies, at a given level of income produced, an increase in the amount distributed as costs of production would be likely to have a different effect upon consumption than would the same reduction if caused by an increase in profits distributed.

[38] Hearings, Pt. 9, *Savings and Investment.*

nearly 37 per cent.[39] On a gross basis national income fell 5.6 per cent, while capital formation decreased 10.3 per cent.

Professor Hansen and Dr. Currie undertook a statistical analysis of the sources of this decline of investment. Dr. Currie's breakdown of his estimates of "income producing expenditures which offset saving," a slightly modified version of the gross investment magnitude, is most convenient for this purpose. Table V provides the gist of his findings.

TABLE V—LAUCHLIN CURRIE'S ESTIMATES OF INCOME PRODUCING EXPENDITURES THAT OFFSET SAVING, 1929 AND 1937[a]

(In millions of current dollars)

Type of Expenditure	1929	1937	Change, 1929–37
1. Plant	4,365	2,175	−2,190
2. Equipment	5,680	5,341	− 349
3. Private housing	2,810	1,450	−1,360
4. Change in inventories	2,146	3,072	926
5. Foreign balance	447	−24	− 471
6. Change in consumer credit	987	891	− 96
7. Non-profit construction	568	190	− 378
Total business and private construction	17,003	13,095	−3,908
Total business and private construction excluding inventories	14,857	10,023	−4,834
8. Government: federal	−235	1,092	1,327
9. Government: state and local	928	−291	−1,219
Total: all governments	693	801	108

[a] Figures for items 4, 5, 6 are taken from Dr. Currie's revised estimates, Hearings, Pt. 9, *Savings and Investment*, p. 4122. His earlier unrevised figures are taken from various tables, *ibid.*, pp. 4011–14, in order to make use of a more detailed breakdown there available.

It is clear that the great changes in the volume of investment occurred outside of the governmental sphere. The increase in the net contribution of the federal government was virtually offset by the decline in the net contribution of state and local governments. Within the private sphere the gross decline came to nearly 4 billion dollars and the decline is even more striking if we exclude from our calculations the investment represented by the accumulation of inventories which was very large in both years but nearly a billion dollars larger in 1937 than in 1929. The decline in private investment excluding inventories amounted to 4.8 billion dollars. The bulk of this decline is easily traced. If we add together the declines in the items that represent construction of one sort or another, that is, plant, private housing and nonprofit construction, the sum is 3.9 billion dollars, which is some 81 per cent

[39] I use here the latest figures of Kuznets, *National Income and Its Composition 1919-1938,* chap. 4.

of the total decline. The volume of construction of both plants and residences was only half as large in 1937 as it was in 1929. The decline in equipment expenditures was small by comparison, less than one half a billion dollars and not nearly so generally dispersed throughout the economy. If allowance were made for price changes, the volume of equipment expenditures may actually have been higher in 1937 than in 1929.

Professor Hansen's and Dr. Currie's presentations of these materials constitute a valuable contribution to our knowledge of recent business history. Specialists, no doubt, will dispute points of detail. The major lesson of the figures certainly will stand. There was a great decline in investment. The decline centered in construction of industrial plant and private housing. Serious controversy begins with attempts at interpretation.

To the present writer three lines of explanation suggest themselves. The first would stress the importance of particular circumstances peculiar to various segments of the field and to the period in question. Thus, one may point out that building construction follows long cycles which vary in duration from fifteen to twenty years. Residential construction which reached a peak in 1925 would, then, not be expected, in the ordinary course, to see another year of high boom before, say, 1940 or perhaps later. Industrial construction which turned down later than residential building would be expected to reach its next high point at a still later date. Moreover, the growth of the power of labor unions and of trade associations which took place after 1933 may well have placed special obstacles in the way of investment in a field notoriously ridden by monopoly in the supply of labor and materials. Investment in railroad plant and equipment was hindered by unwieldy financial structures and bankruptcies which were the heritage of the great depression.[40] The decline in the favorable net foreign balance (nearly half a billion dollars) was due in some part to the recency of our unfortunate experience with foreign lending in the twenties and in some part to the "peculiar" difficulties in international affairs which marked the thirties. This same period saw a decline in the influence of Big Business upon government and a concomitant growth in the influence of farmers and labor unions. It is plausible that the rapidly accelerated pace of governmental intervention in business, the strengthened hand of labor unions, and the novelty of government spending badly shook the confidence of investors. If investment decisions are concentrated in the hands of a particularly small group of men apt to move in the same social circles

[40] Compare Professor Hansen's remarks in this connection, Hearings, Pt. 9, *Savings and Investment*, p. 3547.

and to reinforce each other's prejudices, such an outcome is the less surprising.[41]

A second line of explanation stresses the importance of cyclical factors. The decline of business from 1929 to 1932 was the most serious in our recorded industrial history. From such a deep depression, it is not possible to recover with more than a certain rapidity. Except for temporary inventory booms, time is required for the circular flow of money to be rebuilt, for investment expenditures to have their effect upon consumption, and so to encourage further investment for replacement and expansion. As our economy now operates, the process of expansion creates difficulties by its own working which make the occurrence of a halt very probable after a time. Part of the increased investment which takes place during the expansion represents an accumulation of postponed replacement expenditures. When these have been made, the rate of investment must tend to fall off. Moreover, an important part of the increase in investment associated with expansions is made up of accumulations of inventories required to support a larger volume of production and trade. This rate of investment in inventories depends in part upon the rate of growth of production. If the rate of increase of production slows up, as it generally does in the course of business expansion, this will tend to cause the rate of investment in inventories to fall.

Thus, there was no reason to expect the recovery from the Great Depression to be complete. As a matter of fact the upswing from 1932 to 1937 was the longest expansion recorded in this country since the Civil War, and it was characterized by a far more rapid rate of expansion of national income than took place in any of the business expansions since at least the World War. Net national income rose at the rate of 5.04 billion dollars a year during the expansion 1932-37. The highest annual rate observed in any earlier expansion since 1919 was 3.75 billion dollars in the period 1927-29. In the light of these considerations, one may easily think the last expansion less notable for its failure to reach the national income of 1929 as for the fact that it lasted so long, proceeded so vigorously, and was so nearly complete as it turned out to be.

These lines of explanation, however, are rejected out of hand by Professor Hansen. He proposes a third line of explanation:

> We are completing this year a decade of unemployment on a scale never before known in our history. This decade of unemployment was interrupted by a partial recovery which culminated in 1937. This depression is of a magnitude and duration which has eclipsed all others, not excepting even

[41] See Dr. Altman's estimates of the number of people concerned with major investment decisions: *Saving, Investment, and National Income*, monog. no. 37, p. 89.

the deep and prolonged depressions of the seventies and nineties. It is a unique phenomenon. It cannot be explained in terms of ordinary business-cycle analysis. For the time being at least we are experiencing a chronic maladjustment, a failure of adequate outlets for capital expenditures for a society geared to a high savings, high investment level. We are caught in the midst of powerful forces in the evolution of our economy which we but dimly understand. Something has gone wrong with the forces making for expansion. We are undergoing a fundamental change in the structure of our economic life.[42]

Given this conviction, it is natural to stress the importance of broad changes in the character of investment opportunities, to seek causes whose roots are more deep-seated and permanent than those included in the lines of explanation suggested above. Our recent unfavorable record is, in this view, not merely the result of a deep depression made more serious by its conjunction with other special events. It is a symptom of changes and adverse circumstances likely to fashion our economic history for a long time to come. From the standpoint of people less impressed with these circumstances, it is plausible to emphasize the rapidity and duration of our recent recovery and to blame its incompleteness on cyclical factors and special circumstances. From Professor Hansen's point of view it is natural to explain the duration and rapidity of the expansion by the fact that we had suffered a deep depression and to consider the incompleteness of the recovery as a symptom of more profound causes.

The large capital outlays on industrial plant and equipment in 1936-37 may appear surprising if one accepts my thesis with respect to declining population growth and the lack of important new industries. One must remember, however, that we had passed through a long period of deep depression, so that there had accumulated a considerable volume of depreciation, depletion, and obsolesence, together with the new capital requirements which the rising national income stimulated, but new developments were not available on a sufficiently large scale to sustain for long the high capital outlays of 1936-37, or to push them to sufficiently high levels in view of the lag, particularly of residential building."[43]

Professor Hansen's views about the change in our economic circumstances, the effects of which he believes we are now feeling and are likely to continue to feel during many yars to come, are not unfamiliar. The nineteenth century, he would urge, was preëminently the time when the shop gave way to the factory, hand labor to machinery, and steam power to electrical power. It was also a time of immense improvement

[42] Hearings, Pt. 9, *Savings and Investment*, p. 3503.

[43] From Professor Hansen's testimony, *ibid.*, p. 3515.

in means of transportation and communication which involved enormous investments in their own development and which also made possible the migration of large populations and the exploitation of new resources in the most distant parts of the world. All this technical change and exploitation of newly discovered resources manifestly provided great and growing opportunities for investment.

Concomitant with all this growth of wealth went an accelerating rate of increase in population. As an explanation of the abundance of investment opportunities during the last century, the growth of population is apparently of even greater importance in Professor Hansen's view than were the other characteristics of the period. To this rapid growth of population Professor Hansen attributed the optimistic and venturesome spirit of the capitalists of the time. Overinvestment had to be short-lived in a situation which would soon demand ever greater outfits of plant.

The situation today is far different. The rate of increase of population during the last decade was barely half that which marked the one before it. Our most reliable population estimators assure us that it will be still smaller in the future. The deterioration of international economic life makes large migrations of people and capital unlikely in at least the near future. No technical developments whose investment potentialities are as great as those which marked the development of the automobile or of the railroads are in sight to replace these matured techniques.

There seems to be no way at present to choose among the three competing lines of analysis on grounds which would be compelling to an investigator. Indeed, since the various lines of explanation are not mutually exclusive, the job which is really in question is that of assessing their relative importance—in many ways an even harder task. The present writer is certain that Professor Hansen would admit this; indeed, at many scattered points in his testimony he urges the importance of factors which properly have their place in lines of interpretation rival to his own. If his testimony seems one-sided in these respects it is important to remember that it is natural and right to stress the parts of one's story which are novel and unfamiliar to one's hearers.

Professor Hansen's thesis is more a challenge to work than to controversy. It is clear that much needs to be done analytically to clarify the rôle of population growth. How is it supposed to act? To what extent does it influence the demand for investment goods? To what extent are labor costs affected? In what manner does it modify the demand for consumption goods, if at all? How much of its influence is exercised *via* numbers? How much *via* age composition and family composition? Is it a force independent of a growth of national income

from other sources or does it have an expansive effect only when income is growing?

III. The Operation of the Capital Markets

The conditions which affect the use that can be made of funds comprise only part of the determinants of the rate of investment. The organization and operation of the capital markets and the attitudes of the people who trade in them are equally important. The investigations of the T.N.E.C. emphasize two impressive characteristics of the modern American loan market: the massive rôle played by the great savings institutions and the importance of internal financing of business corporations.

1. *The Principal Savings Institutions*

Donald H. Davenport[44] gave evidence on the growth and concentration of the volume of assets held by life insurance companies, savings banks and other institutions for the accumulation and management of private funds. The figures in Table VI abstracted from his materials present the situation as it stood in 1938.

TABLE VI—ASSETS OF PRINCIPAL SAVINGS INSTITUTIONS, JUNE 30, 1938
(In billions of dollars)

Life insurance assets less policy loans	28.8
Time deposits of commercial banks	14.4
Mutual saving bank assets	11.6
Building and loan association assets	5.7
Total assets of private savings institutions	60.5
Governmental pensions and trust funds	6.2
Postal savings deposits	1.3
U. S. savings bonds	1.2
Total public savings funds	8.7

By tabulating the rate of growth of the assets of these institutions Dr. Altman was able to indicate that a major portion of individual savings now finds its way into the life insurance companies and banks listed in Table VI above.[45] Dr. Davenport presented evidence concerning the degrees of concentration of assets in the hands of these institutions. He found that at the end of 1937 over 50 per cent of the assets of life insurance companies were under the control of the five largest organiza-

[44] *Ibid.*, pp. 3726-74.

[45] *Saving, Investment, and National Income*, monog. no. 37, p. 32.

tions and over 80 per cent under the control of the sixteen largest. Similarly, the 25 largest mutual savings banks held over 40 per cent of savings bank assets at the end of 1938. The 8 largest commercial banks controlled over 20 per cent of the assets held by this class of institution at the end of 1938.

Dr. Davenport was impressed, too, with the extent to which the assets of these institutions were concentrated geographically. This seems clearest and most significant in the case of the life insurance companies which gather their funds from all parts of the country but are located principally in New York and other northeastern states. At the end of 1937 he found that over 75 per cent of life insurance assets were held in New York, Philadelphia and New England.

These compilations of the volume of assets held by savings institutions give particular point to the elaborate investigations conducted by the T.N.E.C. into the operations of the life insurance companies, the largest by far of the group.[46] A great part of the results is no doubt relevant to the investment policies of mutual savings institutions and commercial banks. A convenient summary of the most significant portions of this testimony, so far as it affects the operation of the capital markets, is presented in Dr. Altman's monograph.

An examination of the portfolios of life insurance companies and the testimony of company officials revealed a not unexpected concentration of investments in the securities of relatively old companies whose affairs are more easily investigated and whose safety is least open to dispute. The emphasis upon safety of principal is of course reinforced by legal requirements imposed upon the investment policies of insurance companies. The emphasis upon the securities of our larger and older companies may be a consequence in part of the managerial interrelations between insurance companies, commercial banks and the largest industrial corporations.

Particular companies appear to concentrate their assets in particular forms of investments or in particular sections of the country to the exclusion of other forms and other regions. Thus, one company handles no rural mortgages. Another has a great part of its mortgage portfolio invested in New York City mortgages alone. The explanation is not far to seek. To handle a given class of investments efficiently requires the establishment of an elaborate staff of officials. Specialization upon particular types of investment in particular localities helps to reduce the cost of management. But these facts serve to cast doubt upon the extent to which the concentration of assets in large savings institutions

[46] Pts. 4, 10, 10A, 12, 13, and 28 of the Hearings are concerned with various aspects of the life insurance business.

secures an efficient distribution of loanable funds to the borrowers best able to use them. There can be no question that such specialization must serve to reduce the degree of competition among insurance companies for investments.

Competition for investments is affected, too, by the concentration of assets in the hands of a few large companies. Dr. Altman pointed out that the cash holdings of the 26 largest legal reserve life insurance companies increased by more than 500 million dollars from 1929 to 1938 and that all the executives who were questioned agreed that their cash holdings were greatly in excess of the amount normally required in the business. They claimed that inability to find investment outlets enforced this inconvenient liquidity.

Dr. Altman remarks cryptically: "It would be to the advantage of any one company to invest its surplus cash; and if other companies followed suit, the competition would undoubtedly have a marked effect upon both long- and short-term interest rates."[47]

The significance of this possible absence of competitive fervor is far wider than is suggested by the size of the surplus cash holdings of the insurance companies. Nearly 19 per cent of their total assets were invested in United States government bonds at the end of 1938. If insurance companies hesitated to dispose of their cash for fear of reducing the yield on interest bearing assets, how much more would they fear to disturb the prices of government bonds by selling them and of corporate bonds by buying them?

There can, of course, be little doubt that the large insurance companies are so large that their investment policies are affected to some degree by fears of spoiling the market. But their accumulations of cash in recent years hardly clinch the point. In a period of extraordinarily low interest rates, it is hardly surprising to find large investors holding a great deal of cash and, indeed, of loans of near-by maturity against the chance that interest rates may rise in the near future.

The general significance of these aspects of insurance company operation, moreover, remains questionable in view of the quantities of assets held outside life insurance companies and, indeed, outside all of the principal savings institutions. Dr. Davenport referred to the estimate of the Securities and Exchange Commission that individual and corporate trustees held assets of about 50 billion dollars at the end of 1938. In that year, too, the still expansible assets of commercial banks (less an amount required to cover deposits in savings departments) came to 42.4 billions and an unknown but undoubtedly immense volume of assets was directly controlled by individuals.

[47] *Saving, Investment, and National Income,* monog. no. 37, p. 44.

2. *Internal Financing of Business Enterprises*

The extent to which business depends upon the capital markets for its financing is generally overemphasized. Dr. Altman[48] presents estimates which compare the gross savings of business enterprise with George Terborgh's estimates of outlays for plant and equipment. The figures presented make it clear that during the period covered, 1923-39, by far the major part of plan and equipment expenditures were financed by the internal funds of business.

Dr. Altman also presents Arthur Hersey's figures on the sources and uses of funds for 58 large industrial companies which cover roughly one-fifth of all manufacturing and mining. During 1930-39 these companies required the use of 5.5 billion dollars almost entirely for investment in plant and equipment. Only 10 per cent of these funds were secured from sources outside of the companies themselves. Gross savings provided 83 per cent of the required amount and the conversion of assets supplied the remainder.

Dr. Altman poses a dilemma. It seems clear that the larger and the better established firms in the United States have little need to borrow funds in the open market. But it is these firms which have the easiest and cheapest access to the capital markets as these are now organized. It is not clear that, as the capital market now functions, the job of putting savings of individuals into the hands of willing borrowers is efficiently performed.

IV. The Remedies Proposed

None of the witnesses or monographists undertook to set out a systematic statement of the policies which they considered to be most effective in filling the gap between the quantities which they believed people would wish to save and invest at high levels of income. Professor Hansen and Dr. Altman, who came closest to doing so, were both more concerned to state the nature of the problem to be met than to prescribe a detailed course of action. Thus, we are told at many points that if private investment, in the ordinary course, is not sufficient to offset savings at high levels of income our policies must be directed to increasing private consumption, stimulating private investment, augmenting private consumption by communal consumption, and private investment by public investment.

The statements of these writers about specific policies indicate a tolerance for most, if not all, of the chief devices for securing these objectives which have been proposed in recent years.

[48] *Ibid.*, p. 57.

Both Professor Hansen and Dr. Altman agree that our system of taxation requires overhauling primarily to reduce the burden which our levies now place on consumption. They would reduce excise and pay roll taxes and raise the required sums by increased taxation of the middle income groups.[49]

Professor Hansen argues that private investment can and should be stimulated by measures designed to remove those aspects of the corporate tax structure which have repressive effects upon expansion;[50] by securing "stable and responsible labor relations";[51] and by requiring "adjustment of prices to the lower costs springing from technical improvements in order to tap potential demand and thus secure larger output, and thereby also larger capital plant and equipment expansion."[52]

Dr. Altman and Professor Hansen both point to certain obstacles in the way of increased building construction: unduly high interest rates, monopoly prices for labor and materials, inadequate supervision of construction, cumbersome foreclosure and tax sale procedure.[53]

Dr. Altman emphasizes the lack of a capital market adequately organized to supply the needs of small and medium sized business.[54] In this connection Adolph A. Berle's suggestion that a new set of commercial banks be created specifically to furnish longer term credit than our present commercial banks habitually do is of interest.[55]

Finally, public spending to augment private consumption and investment is strongly urged by these witnesses.

Among these many proposals for reform and action, heaviest emphasis was placed upon two lines of action: first, a reconstitution of the tax system to reduce the communal propensity to save; and, second, public spending to augment the volume of investment. The discussion of the second of these proposals need not detain us long. In the T.N.E.C. testimony the efficacy of public spending is taken for granted, its limitations neglected. Certainly nothing was presented which advanced the argument so heatedly pursued in the last decade. The policy of tax reform, however, deserves a longer glance because its potentialities can be somewhat illuminated by the use of the T.N.E.C. materials.

1. *Potentialities for Increasing Consumption by Tax Reform*

The estimates of tax burdens and savings by income groups presented by Dr. Colm and Miss Tarasov[56] make possible some preliminary guesses about the effect of a redistribution of tax burdens upon individual savings. The Colm-Tarasov figures are, admittedly, extremely rough estimates of the distribution of income, savings and tax burdens. The authors are careful to emphasize their dependence upon inadequate samples, extrapolation in time and indirect evidence. Estimates of the effect of a redistribution of tax burdens upon savings will, of course, inherit all the errors of the basic data and add some of their own. It seems wise, nevertheless, to attempt to secure some notion in quantitative terms of the probable consequences of a program of tax reform.

Rough calculations by the present writer indicate that a truly enormous shift of taxes from the relatively poor to the relatively rich would be required to effect a substantial reduction of savings. In the fiscal year 1939, the year to which the Colm-Tarasov figures refer, the present writer estimates that a 30 per cent reduction of the amounts people desired to save (aggregate income being constant) would have involved the extinction of all taxes on the incomes of families earning less than $2,000 a year and the distribution of this burden among higher income groups.[57] The groups so relieved of taxation contributed in 1939 no less than 45 per cent of total tax revenues. Moreover, since the taxes on the lower income groups are levied mainly by states and local govern-

[56] *Who Pays the Taxes?* monog. no. 3.

[57] The calculations upon which these results are based involved the following major steps: (References are to Colm-Tarasov, *op. cit.*)

1. The tax burden borne by families earning less than $2,000 in 1939 was distributed among the better-paid groups. This was done in two ways: first, in proportion to the total income earned by these groups, and, second, in proportion to the taxes actually paid by these groups. The first assumption places a heavier relative tax burden on the middle income groups than they now bear. The second assumption maintains the degree of progression which now prevails for groups earning over $2,000.
2. Total income *per capita* after taxes was then calculated for each income group before and after redistribution of the tax burden. For this purpose, estimates of the number of families in each bracket found in Table C, p. 42, were utilized.
3. The amounts actually saved by each income group were found in Table 1, p. 6, and the percentage which savings were of income after actual taxes calculated for each group.
4. The rate of increase in percentage of income after taxes which was saved for each dollar of increase of per capita income was then found by dividing the differences in percentage of income saved by successive income groups by the differences between income brackets in income per capita after taxes.
5. These figures were then used to calculate the change in percentage of income saved due to the changes in income associated with each assumed redistribution of the tax burden.
6. Finally, the percentages gained (from 5) were applied to the total income after taxes in each income bracket after redistribution of the tax burden.

The amount actually saved in 1938-39 as estimated by Colm was 7.97 billion dollars. The two methods of redistributing the tax burden used above indicated reductions of savings of 26 per cent and 31 per cent respectively.

ments, what is involved is nothing less than the stupendous task of local rather than of national fiscal reform.[58]

A redistribution of the tax burden, moreover, meets more than administrative difficulties. Its objective for our present problem is a reduction of the realized income of the rich, a transfer of the proceeds to the poor. By their very nature, however, progressive income taxes operate as an attack not only on high *realized* incomes but also as an attack on the *prospective increases* in income which people hope to secure by investment. Thus, while a more progressive system of taxation should operate to increase the rate of spending, it should also operate to decrease the rate of investment. These difficulties, administrative and theoretical, make the possibilities of securing a substantial net increase of national income by tax reform appear more modest than they are usually assumed to be.

Tax reform, however, is not the only way to secure an increase in our average propensity to consume. The elimination of monopoly controls and restrictions, by reducing profits, operates in the same direction. Moreover, this process, while it tends to reduce profits and therefore savings, also acts to increase investment. As such, it is a useful supplement both to a program of tax reform and to a program of public investment.

This double-barreled influence of an increase of competition deserves more stress than it appears to have been given in the materials reviewed. The pages which follow are, therefore, offered as a statement of the connection between competition and the propensities to save and invest. This statement is in no sense an attack upon those who contributed to the valuable work of the T.N.E.C. Its purpose is simply to add a useful rider to their efforts.

2. *The Monetary Consequences of Competition*

First to be discussed is the effect of monopoly restrictions upon the rate of investment. The consequences which may be expected from

[58] A simple increase of income taxation would, of course, eat still further into savings, provided the burdens fell largely on the relatively rich and the benefits accrued largely to the relatively poor. In a note entitled "The Incidence of an Income Tax on Saving" (*Quart. Jour. of Econ.*, Feb., 1942, pp. 337 *ff.*), Professor Abram Bergson presents estimates of the effect upon saving of an increase in income taxation amounting to 5 per cent of incomes received in the fiscal year 1936. Proceeding by methods somewhat similar to those described above, Professor Bergson finds that an additional tax of this magnitude would have reduced savings by 30.1 per cent if levied in such fashion that the then existing degree of tax progression was maintained. Had the tax been levied so as to maximize the reduction of savings, the decline in savings would have been 32.3 per cent. Professor Bergson is careful to point out, however, that these figures overstate the magnitude of results to be expected. No allowance is made for the effect upon incomes of the expenditures of the additional revenues or for any possible decline in investment consequent upon an increase in income taxation.

the establishment of a more intense degree of competition may conveniently be discussed under two heads: first, the initial consequences which are involved in the process of establishing freer competitive conditions; and second, the longer run aspects of the comparative attractiveness of investment in relatively monopolistic and relatively competitive markets.

If competition can be made more free, the rate of investment is likely to increase initially for three reasons.

One aspect of the improved situation will be a reduction in the obstacles facing firms which wish to share in the opportunities afforded by hitherto profitable industries. We should, therefore, expect investments to be made by newly organized firms previously excluded from tempting markets.

A second consequence of more intense competition is an increase of aggregate output. This is the result of two factors associated with competition: lower prices and increased cost of output. Lower prices have an obvious and direct effect upon amounts purchased. An increased cost of output operates indirectly. It constitutes a shift of income from profit makers to their hired factors of production and should act to raise the ratio of national income spent.

Now it seems reasonable to assume that the production of a greater volume of goods will necessitate the use of a greater volume of fixed equipment. There would seem to be but one important qualification to be borne in mind. To the extent that commodities were previously produced by firms operating at other than the optimum scale of output, competition which involves an approach to the optimum scale of output per firm will act to reduce the amount of resources required to produce a given output. And this factor will tend to offset the effects of the increased production of goods.

The process of establishing freer competitive conditions will make its influence felt on the rate of investment in still a third way. More intense competition will serve to reduce the prices not only of consumers' goods but also of producers' durable goods. Any decrease in the price of producers' durable goods should lead business men to increase their total real investment in these goods.

So far we have been discussing the initial effects upon investment of an increase in competition. The effects in the long run turn on a somewhat different set of considerations. As a continuing matter, investments may be said to be occasioned in seven principal ways:

1. New resources are found or made accessible and are drawn into production when the necessary funds are laid out.

2. Improved techniques of production are found and more efficient

equipment invented, the exploitation of which involves an investment of capital.

3. New products are devised and offered for sale; and this usually, though not always, involves an investment of funds.

4. Relative prices of equipment and labor and of equipment of different sorts change and thus new methods of production become profitable.

5. Demand shifts from one sort of commodity to another and this may sometimes involve investment at a rate greater than the depreciation of equipment in the lines adversely affected by the shift in demand.

6. The exploitation of new resources and of cost reducing improvements, by lowering costs of production, acts to increase the total real income of the economy and this, in turn, creates opportunities for investment.

7. Finally, in industries in which the obstacles to investment are not too great, constant attempts to establish a profitable niche for themselves are made by eager investors.[59]

We turn now to consider how freer competitive conditions will influence the rate of investment in connection with each of the opportunities for investment mentioned above. It is clear to begin with that profitable opportunities to bring new resources into use are far greater in situations in which the obstacles to securing a market are minimal than in conditions where these are great. In the perfect market of theory where obstacles to entry are completely absent, it will pay new firms to exploit newly discovered or more accessible resources whenever the average total costs of production, using the new resources, fall below the average total costs of production for firms operating under the previously existing conditions. By contrast, firms already operating find it profitable to exploit new resources only when their use drives average total costs of production below prime costs in the previously existing situation. Any expense involved in establishing a market for a potential producer with new resources serves to increase the degree to which the new resources must make possible a reduction in costs before their exploitation is profitable.

Exactly the same comments apply to the question of the introduction

[59] Some substantial portion of our annual rate of net investment must be accounted for by these last mentioned attempts, successful and unsuccessful, to secure a business market. Of course, to the extent that these attempts constitute a net inflow of resources into an industry, we have already taken them into account in the section dealing with the initial effects of establishing more competitive conditions. There is an additional point here, however. An investment of $1,000 that forces the abandonment of an investment worth an equal amount increases the demand for investment goods by $1,000; it decreases the demand only by the annual rate of depreciation on investments of the character in question.

of newly devised and more efficient machinery or techniques of production. So far, then, as the discovery of new resources or techniques is independent of the degree of competition, it is clear that in relatively competitive conditions there is a greater incentive to exploit these emerging opportunities than exists in relatively monopolistic markets.

The availability of these opportunities, however, is probably not independent of the degree of competition. In the first place, it would appear that the search for new resources and new techniques would be fostered by the existence of open markets in which their products could be sold. As a protective measure, firms threatened by the possibility of such discoveries would try to make them themselves.

On the other side, it may be urged that large firms will be better able to accept the risks attendant upon research and exploration than will small ones. It is not clear, however, that in all cases, or even in most cases, an increase of competition would involve a decrease in the size of firms. But even if it be admitted that a split-up of large firms would reduce the amount of funds which the successor organizations would devote to research, the very same conditions are likely to see the organization of enterprises specializing in the work of exploration, scientific and geographical. Moreover, a well-conceived governmental policy looking to the disestablishment of monopoly might well carry, as one of its corollary features, an increase in the amount of government funds devoted to the pursuit of industrial research.

Similar considerations are involved in the case of investments designed to bring new products to the consuming public. In this case, a new producer will find it profitable to offer an improved product whenever he considers that its sale will cover its average costs of production, including such promotional costs as are necessarily involved. Any obstacles which existing firms can put in his way serve to discourage the investment. So far as existing producers are concerned, the obstacle to offering new products consists, in some part, in the fact that the new products will serve to take demand from their older commodities. A more important obstacle, however, is the fear that an improved item may not meet success because competitors will be induced to offer similar products. The strength of such obstacles varies directly with the size of firms relative to the size of the market area in which they operate and with the effectiveness of agencies for promoting exploitative coöperation among producers.

It is clear that the incentive to invest in order to promote new products is weakened by the existence of monopolistic arrangements. But qualifications should be attached to this statement similar to those made in the case of investment to exploit new resources or techniques. While

the incentive to promote new products is greater in competitive markets, it is not certain that the funds devoted to their discovery and perfection will be so great.

We must next consider the effects of changes of relative prices. Such developments make the immediate introduction of modified methods of production profitable for new firms. For established firms this is true only if total costs using the new methods are lower than prime costs with the old. It is certain, therefore, that investment will respond to changes in relative prices more continuously and completely in industries into which entry is easy than in those into which entry is difficult.

The fifth and sixth occasions for investment, increases of aggregate demand and shifts in the direction of demand, may be conveniently considered together. In neither case is the result clear. The response of investment either to an increase of demand in industry as a whole or in particular industries would seem to depend on two considerations: (1) the effect of an increase in demand upon output in an industry organized in monopolistic fashion as compared with the effect of the same increase in a competitive industry; (2) the relative effect upon investment of a given increase in output in the two situations.

While it may be argued with a high degree of plausibility that output in a competitive industry would be greater than in a monopolistic industry, it is not clear that an increase of demand would result in a greater increase of output under competition than under monopolistic conditions. Nor is it quite clear that a monopolistic industry would make a greater or smaller investment in response to a given increment of output than would a competitive industry. The character of the conditions of supply of equipment and of other factors of production to the industry will determine the issue. This section of the argument, therefore, reaches inconclusive results.

Seventh and finally, it is clear that a general reduction of obstacles to the entrance of new firms into industry will increase the demand for investment goods from that routine category of enterprisers who are constantly seeking by repetitive methods to secure an established place in industry.

The weight of the argument thus far has been strongly in favor of the notion that the destruction of monopoly controls will make for a higher rate of new investment, both immediately and in the long run. It may be thought, however, that an important qualifying circumstance has been overlooked, namely, the relative degrees of risk associated with monopoly and competition respectively. Will not business men feel that an increase of competition increases the risks of enterprise; and will they not, in consequence, be less eager to commit their funds?

This may, in fact, be the case; but it is a qualification which attaches to our argument concerning the immediate rather than the continuing effects of an increase of competition.

It was argued above that, if the many real obstacles to investment associated with monopolistic controls were reduced and if the prices of producers' and consumers' goods fell, this would lead to an immediate increase of the rate of investment. It would do so directly because new firms would seek to share in the profits of existing industries and because the prices of producers' goods had fallen. It would do so indirectly because the volume of consumers' goods demanded would have risen in consequence of lower prices and lower profits.

If, however, an attack on monopoly controls enormously increases business men's fear of potential competition, this argument is certainly weakened. Investors previously balked in their desire to join an industry will be less eager to commit their funds when the obstacles in the way of other potential investors are reduced. In extreme instances, it may be supposed that, instead of new firms joining an industry, old ones would withdraw. This seems implausible, but the theoretical possibility cannot be denied. To the extent that it operates, however, the indirect stimulus to investment is also somewhat weakened. The increase of demand which we suggest would flow from the reduction of profits will not be so great. All this, however, does not touch the other sources of immediate encouragement to investment: lower prices for producers' equipment and for consumers' goods in general.

More important is the fact that the degree of fear of potential competition is not a factor relevant to our argument concerning the long-run incentives to new investment. For this purpose we must compare industries which—aside from the emergence of additional opportunities to invest—are in equilibrium, that is, both the relatively monopolistic and relatively competitive groups which we compare are adjusted to the degree of potential competition associated with their respective markets. The question at issue is: Which group (potential competitors included) will respond in greater degree to its emerging opportunities to invest? The argument above indicated that a greater response is to be expected in situations in which potential competitors face fewer obstacles in securing a market or access to materials and equipment.

So much for the relation between monopoly and the rate of investment. Next to be considered is the connection between monopoly and the propensity to save. It has been pointed out that the volume of realized profits is perhaps the most important single cause of inequality in the distribution of income and, therefore, of our propensity to save. An effective attack upon the propensity to save involves an attack upon

high realized profits. The difficulty is to attack the realized profits of existing investments without attacking the prospective profits of new investments. Progressive income taxation falls foul of this hazard; it hits the one, but it fails to miss the other.

As a supplement to, and perhaps in part as substitute for, a program of progressive taxation, consider the claims of an attack on monopoly. It is clear that the destruction of monopoly positions will involve a lowering of the rate of realized profits. It will do so, first, by encouraging the organization of competing firms to share in a given volume of business. This will mean either an increase of average costs of production or else a wider distribution of the same volume of profits. It will act in the same fashion, secondly, by promoting lower prices or higher wages or the expenditure of funds to promote sales.

A lower rate of profits in turn means a tendency to lower *aggregate* profits if the assets carried by industry for a given rate of output are no larger under competitive than under monopolistic conditions. This seems to turn on two conflicting forces. In the first place, monopolistic firms may carry larger or smaller assets than competitive firms producing the same volume of goods. The outcome turns on the conditions of supply of factors which will be different to monopolistic and competitive firms respectively. While total costs for firms of the same size are likely to be lower if the firms are monopolies, there is no general reason to suppose that the economies will be gained in the use of capital assets. So far as this factor goes, then, the outcome is inconclusive. But, secondly, since firms in industries marked by price competition are likely to be operating more nearly at optimum scale than are firms in monopolistic markets, the assets held by an industry for a given scale of output are likely to be smaller in competitive situations. So far, then, as this qualitative argument can take us, we are led to the conclusion that competitive industries are likely to hold a smaller quantity of assets and to earn a lower rate of profit on them. Aggregate profits earned in connection with a given rate of output should, therefore, be smaller under the competitive conditions.

While this merely indicates the direction in which an increase of competition would operate, no one can read the many volumes of T.N.E.C. monographs and Hearings dealing with monopolistic restraints upon business without being impressed by the ramifications of monopolistic controls and the probable extent of monopoly profits.

An increase of competition, then, like an increase of taxation, is an attack upon inequality in the distribution of income. As indicated above, however, it operates by increasing the inducement to invest rather than by reducing it. The profits realized by monopoly act to

increase the rate of saving. The profits made in a competitive industry, it is true, also act to increase the rate of saving, but they constitute an open invitation to investment. To put the matter categorically, a regime of monopoly means high profits which tend to be hoarded; a regime of competition means lower profits which tend to be employed.

PRESENT POSITION AND PROSPECTS OF ANTITRUST POLICY

By Myron W. Watkins

I—Antitrust at Crossroads

It is a commonplace now that the Sherman act was a product of its time. More than a commonplace, an adage, is *O tempora, O mores*. Admittedly the times have changed. Methods of production have been revolutionized by the advent of electric power, automatic machinery, and industrial chemistry. Methods of distribution have been wrought into a new pattern by the development of advertising, automotive transportation, the radio, consumer finance. The accepted ways of life are not what they used to be. But it does not follow, as some would have it, that therefore the antitrust law of 1890 which still defines the basic policy of American government in the regulation of trade and industry is outmoded, in line for displacement. It may be. Equally, it may not be.

Whether antitrust policy has become an anachronism, however well or ill adapted it may have been to the exigencies of the times which gave it birth, depends, first, upon what one understands to be the essence of that policy as now interpreted and applied, and, secondly, upon what one conceives to be the significance of the changed conditions which now confront us. At what does the Sherman act really aim? What does its enforcement or attempted enforcement actually accomplish? What do the changes in the contemporary economic environment, industrial processes, and commercial practices connote or portend? What do they require by way of apt rules for industrial governance? Preliminary to essaying an answer to these questions, it might be well to inquire briefly concerning the circumstances which have occasioned them.

Undoubtedly a large factor in calling antitrust policy into question was the bitter experience of the long depression in the early thirties. It was not only that revulsion developed toward an economic policy which could not prevent such unprecedented losses and such intolerable misery. There was also the sense of frustration in having available abundant resources, unmatched equipment, and millions of men eager to work—yet idle, withal, for want of an opportunity. A (legally) free market instead of providing an outlet for ingenuity, industry, and enterprise seemed to be a device especially designed for thwarting

native impulses toward economic provisionment. Few there were to protest, therefore, and a multitude to support, the New Deal experiment of shelving a free market, suspending the antitrust laws, and attempting to run industry by a combination of generous subsidies to the "under-privileged" and free-handed sanctions to the "specially-privileged." The results of a policy of self-regulation of industry by majority rule, as exemplified in the N.R.A. codes and their administration, were not as salutary as the sponsors of the movement had hoped. They were still less heartening to the general public. Though the collapse of the N.R.A. left few mourners, there was observable no spontaneous reaffirmation of faith in the efficacy of competitive forces working through free markets to regulate and direct the economy in the interests of the common welfare. Antitrust policy was reinvoked, not because it promised stability and "plenty," but because it was the only alternative ready to hand.

This was shown, in one way, by the institution of a comprehensive Investigation of Concentration of Economic Power by the 75th Congress. The Temporary National Economic Committee was created in hearty response to a Presidential Message of April 29, 1938, which set forth lucidly the grounds for continued exploration in quest of a public economic policy which would afford greater assurance of full utilization of resources without sacrifice of freedom. The extensive Hearings conducted by the T.N.E.C. and the forty-five monographs prepared at its instance are the subject of review in this volume. But at this particular point it is not so much the significance of the data assembled and of the studies made, or of any single aspect of them, to which attention is directed as it is the fact of the survey being undertaken, zealously prosecuted by able men from numerous branches of the public service, and followed with keen interest for three years by the general public. Not since the stormy days of the United States Industrial Commission at the turn of the century has there been evident a popular concern so deep, so wide, and so eager over the issues of public economic policy, over the question: Industrially whither? Manifestly, Antitrust is at the crossroads.

Misgivings growing out of domestic experience have been quickened by the trend of events abroad. The rise of fascist statecraft and the rebirth of economic autarchy have circumscribed the area of free market adjustments and generated cumulative difficulties for prudent investment and provident management by free enterprise in the areas where it is still permitted to function. Indeed, these developments have raised profound doubts that the luxury of freedom can indefinitely be afforded in a world economy ruled so largely by political forces for political ends. These doubts are not allayed by the actual

spectacle of a ruthless regimentation of the economic resources of whole nations, and now of whole continents, for purposes of nationalistic aggrandizement.

The war which was thus bred could not be isolated. As it spread over three-quarters of the globe it steadily became more apparent that more and more warlike preparations for defense from the encroaching menace were required. The national defense program inaugurated in May 1940, and the lease-lend program adopted a year later were the outward expressions of a growing conviction that war, like peace, is indivisible. When, finally, on December 7, 1941, Pearl Harbor was blasted by a treacherous "friend," there was none to gainsay that all-out action on this conviction could longer be deferred. But no more for preparations for war than for the conduct of war itself are free enterprise, free markets, and free competition adapted. These are devices by which the resources of a community may be directed toward ends which reflect the voluntary choices of the individuals composing the community. They tend to supply what men want. But men do not "want" war. If the community is to be prepared for war, still more if it is to win a war, it must put aside the ways of peace and become a warrior: it must give up the vocations it prefers and the goods it wants and concentrate its resources and its energies upon making the implements of warfare. There is no other way to accomplish this effectively, as we learned from experience a quarter-century ago and as current exigencies are teaching us again, than by drafting a common program and taking concerted measures, if need be coercive measures, to secure its fulfillment on schedule.

It is not that the common welfare needs to be invoked only in time of war and may safely be disregarded in time of peace. The common welfare is always paramount. But in a period of emergency what constitutes the common welfare is something very different from what it is in ordinary times. "Plenty" and security are not the same thing. Furthermore, the means to the attainment of these ends differ. For the government not only to sanction free enterprise generally and to make public enterprise an exception, but also to safeguard freedom of access to markets and to enforce competition may be wholly consistent with the promotion of the common welfare in terms of "plenty" and nothing less than a disastrous blunder in other circumstances, when survival is at stake.

This is not to say that antitrust policy, the enforcement of the antitrust laws, can serve no useful purpose in periods like the present. There is still need for vigilant extirpation of privately contrived barriers to enterprise, restrictions on production, and price manipulation. In not all segments of the economy have the exigencies of defense, or will the

exigencies of war, require or lead to a complete supersession of the market. Moreover, the mere fact that the government finds it necessary here, there, or elsewhere, itself to erect barriers to entrance to or exit from a trade, to impose restrictions on production, to establish priorities in distribution, or to fix minimum or maximum prices, provides no license for private interests to fill in the gaps in these regulations by arbitrary or collusive measures of their own. Indeed, one may be justified in concluding from some of the revelations of the Special (Senate) Committee investigating the National Defense Program, not to mention World War experiences, that in these very circumstances there is a special need of vigorous enforcement of the antitrust laws. The opportunities for favoritism, discrimination, predation, and extortion are always at the peak when an economy is operating in high gear, whether or not the acceleration of business activity is induced by war orders. And beyond the jeopardy to consumer interests by direct manipulation of markets thereby facilitated, there is the by no means fanciful possibility of the improvised agencies of administration being imposed upon, having their functions perverted, by combinations of special interests which are still bent upon "business as usual," still nourishing the convenient illusion that the public interest and their interests are always and everywhere identical.

Nevertheless, the obvious and admitted inadequacy of antitrust policy to assure that the resources of the community will be expeditiously and efficiently mobilized for defense and for war has had its share in impairing public confidence in the soundness of that policy. For the deficiencies in our preparedness for war, even after two years of unmistakable warning, were clearly not confined to those of a directly military character. Notwithstanding that its adaptability has been conceived to be one of the primary sources of strength in a free enterprise economy, there was plainly something—stemming perhaps from recent trends in the structural features of the national economy, perhaps from unwonted and obscure forces shaping the operative policies of business, perhaps from emergent tendencies affecting the fundamental human relationships in industry—which resisted and retarded the process of economic adaptation to war. The emergency has only served, thus, to strengthen the conviction that a reëxamination of the very bases of public economic policy is in order.

II—Nature, Objectives and Implications of Antitrust Policy

Antitrust policy rests upon certain assumptions. Just because these assumptions are so often left implicit in its formulation or defense, they warrant summary restatement. It is assumed that men are economic

prime-movers, not passive slaves of circumstance. It is taken for granted that individuals know their own interests and are vigilant in defending them, resourceful in pursuing them. They are not supposed to resign themselves readily to accepting what comes; rather they have the initiative to go in search of what they lack and to persist in the quest, only spurred by each lack overcome. In sum, the human animal is conceived to be dominated by irrepressible inner drives. This may not be the polar opposite of the conception of human nature with which the behaviorists have familiarized us, but it has many elements difficult to reconcile with that view.

It is assumed, in the second place, that the economic environment is characterized by an abundance of opportunities.[1] Nature has not been too niggardly in supplying the raw materials of existence. Natural resources are available to be turned into the means of livelihood by an industrious populace, endowed with a workmanlike bent. In a measure, this condition has doubtless always obtained, but it certainly obtained in a higher degree, considered relatively to the size of the population, in America in the nineteenth century while there was yet a frontier of virgin forests, untracked prairies and untapped mines than it does today.

In respect to technology, the situation presupposed for the effective operation of competitive markets of the type (characterized by a multiplicity of independent enterprises forthrightly contending for patronage) which antitrust policy is designed to implement and promote is one in which knowledge of the accredited ways and means of production is accessible to all, or at any rate to a great many. Not only that, but the capacity for acquiring and applying that knowledge is assumed to be well within the reach of the vast majority. This means that the technical processes prevalent in industry must be comparatively simple and readily comprehensible. The technical equipment required for these processes operating on an economical scale is assumed to be no more extensive than numerous individuals or voluntary groups can command. Handicraft and husbandry come close to fulfilling the technological conditions for a workable antitrust policy of the nature of that with which we are familiar. In the past half century, however, the situation in this respect has departed somewhat markedly from that on which the established antitrust policy is premised. The advances made by modern technology since 1890 have in many fields raised an all

[1] Of course, this does not imply that the society must be "poor," much less that it must be "rich." It has no reference at all to the volume of accumulated wealth. What it does refer to is potential wealth, and this in the form of readily accessible resources, nature's "bounty." The condition might be described otherwise, and perhaps not less significantly, as one of a high degree of expansibility.

but impenetrable barrier to independent enterprise. Only a comparatively few can be expected to master the technical problems or even to acquire an understanding of the esoteric technical jargon of those who do devise the complicated formulae and processes of industries such as rayon, electrical apparatus, or air-conditioning, for example. Quite aside from patent privileges and capital requirements, in a wide range of manufacturing industries technological conditions have severely limited the opportunity to engage in production, however beguiling the profit prospects may be.

On the legal side, antitrust policy has never been self-sufficient. It has always assumed the maintenance by government of the sanctions of property rights, contract rights, and various civil rights. Without these sanctions, without the readiness of public authority to vindicate these private rights whenever they might be invaded or infringed, there could be no competition to be regulated; for there would be no market in which products are voluntarily exchanged. It is manifest that the antitrust laws are no more than a supplement to the law of property, of contracts, of torts, and even of crimes. The type of economy, or of economic behavior, which the antitrust laws posit and seek to cultivate is only a reflection of the type of society which the entire legal system, including the Constitution, is designed to foster and conserve.

The fabric of social-economic institutions in which antitrust policy is rooted is not easy to describe. For one thing, it does not stay put. It changes continually. Yet its changes are not always perceptible. Its nebulous content does not facilitate comprehension of the inwrought design, let alone of the shifting pattern. Settled usages, traditional habits of thought, accredited canons of behavior, sanctioned goals of endeavor—these are the stuff of which the institutional fabric is made up. These are what compose "the American way of life." Just because they envelop and mold our every act, our most transitory thought, they evade analysis. They are taken for granted. In ordinary circumstances, we are too familiar with them, and too unfamiliar with their potential alternatives, consciously to reflect on their distinctive features or to probe their essential meaning. Yet in times of crisis, no less of society than of the individual, self-examination is invited, if it is not indeed imperative.

The institutional scheme of which antitrust policy forms an integral part is one which, may we say, honors the individual. It does not glorify the state. It treats the state as an instrument. It respects the common man's addiction to the pursuit of self-appointed ends. It erects no *summum bonum* other than the sum of the individual "goods" which emerge from the self-directed efforts of a free community. Divergences among these self-directed efforts and differences in these self-appointed

ends are not only tolerated; they are welcomed. The basic framework of government is designed, indeed, far more to safeguard rights than to impose duties. Common sense and common decency, backed by the common will, are trusted to secure, to a workable degree, voluntary accommodation and the mutual, pacific adjustment of conflicting interests. In this fashion the strength and resourcefulness of the individual is cultivated. In this fashion, the capacity of the organized community for survival is fostered by a spontaneous process of continuous adaptation to the ever-changing conditions of livelihood.

All this may be as repellent, to some, as brackish water from a stagnant pool. But it may also have the flavor of well-aged wine. The taste depends upon the palate. That a society so constituted has, or may have, certain elements of rugged strength, a capacity not only for survival but for growth, and a capacity for growth not alone in numbers and in wealth, but as well in cultural amenities and intellectual horizons is attested by the history of the past century. For that matter, it is attested by the record of the past five centuries, to go back no farther. But the question remains: Does it still have, does it have today, in this century, the same survival value it has had in times past? Or has the range of free opportunity become so constricted with the preëmption, exploitation, and exhaustion of natural resources, and with the displacement of a technological use and wont, which were a common heritage by a technology that lent itself to usurpation as a special privilege, that the appeal of self-responsibility and the prospect of self-advancement have lost their hold upon the common man? Can the modern economy much longer be effectively organized in terms of private rights instead of in terms of public duties?

This much may be confidently said: In approaching an answer to these questions account must be taken of the emergence of a deep-seated conflict in the institutional patterns on which contemporary society is organized. On the one hand, business arrangements are made, trade conducted and employment secured within the framework of this traditional "system" of free private enterprise in free markets. The procedure is by way of transactions. The units of economic organization and industrial action are individuals and voluntary associations (corporations, trade unions, coöperatives). The apparatus of industrial government consists largely of three elements: self-control and the mutual checks of competition, supplemented and reinforced by a variety of legal inhibitions, of which the antitrust laws are a conspicuous example. On the other hand, there has grown up within, perhaps one should rather say behind, these forms of business organization an industrial system patterned on the machine technique. The essence of that "system," as of any machine, is deliberate differentiation of func-

tion and artful integration. In so far as any process is conducted on the model of the machine technique, procedure by way of transactions is anomalous. The parts are interdependent. They must be fitted together and operated as a unit. Were needle and bobbin subject to independent controls, the sewing machine would ill serve its purpose. The "free play of competitive forces" among the parts of a machine spells friction, inefficiency, breakdowns.

The intention need hardly be disavowed of arguing that American society *should* be made over on the mechanical model.[2] The point is simply that, in industry, it has for at least a half-century been undergoing transformation in that direction. And the habits of thought and ways of behavior thus engendered cannot be confined to the seven-hour day on the assembly line. *Pari passu* with the advances of the machine technique in industry has come a progressive standardization of ways of life, an increasing social and economic integration, which, whether we like it or not, unquestionably tends to check, or restrain, enterprise. For these developments at once restrict the range of opportunity for individual initiative and weaken the impulse thereto. They tend to devitalize competitive forces and deprive a free market of its *raison d'être*.

All this is not to say that the technological forces making for standardization and integration may not be counteracted. Much less is it to subscribe to the *non sequitur* that whatever is, is right. There was, fortunately, in the proceedings of the T.N.E.C. no disposition evinced to accept the naïve assumptions that, in shaping an economic order, there are any "inevitables" stemming from technology and that a meliorative trend is foreordained by an inscrutable providence. But if a free society is to endure and an economic organization compatible with it to be rebuilt, there is advantage in recognizing the sources and the strength of the antithetical tendencies which pose the problem and which have to be dealt with. To release the vital impulses of a generation which has become habituated to mechanical routine, more will be required than a reaffirmation of old formulae and a revival of familiar expedients.

[2] Perhaps a caveat might not be out of place here, also, against interpreting the foregoing observations as an explanation, much less as a defense, of industrial concentration in terms of technological expediency. The discussion has to do with the significance of the machine technique as a social institution, *i.e.*, as a pattern of human behavior. It is not concerned with the advantages, real or putative, of mechanization of industrial processes and their bearing, actual or alleged, on the growth of Big Business. For those who may be interested, the writer's view on this latter issue has been fully expounded in his book on *Industrial Combinations and Public Policy* (Boston, 1927), chap. 4; in his article on "Large Scale Production," in the *Encyclopedia of the Social Sciences*, Vol. IX, pp. 170-81; and more recently in a memorandum for T.N.E.C., published in *Relative Efficiency of Large, Medium-Sized, and Small Business*, monog. no. 13, as Appendix A.

III—The Scope of Antitrust Policy

In a reëxamination of antitrust policy it is well to recognize, as it was generally recognized in the Hearings and the monographs of the T.N.E.C., that the policy was not designed and does not operate as the exclusive, exhaustive embodiment of public economic policy. It is only one segment of the pattern of industrial government, even though the scope of its application may be broader and its influence on the general welfare, the fruitfulness of economic endeavor, more decisive than those of any other single segment. There are important sectors of economic activity to which it does not apply at all, as in the field of government services. In this sphere, competition may be authoritatively excluded, as in the case of police, postal, and sewage-disposal services. Or, though competition may be tolerated, as it is, for example, in the provision of meteorological information, recreational parks or education facilities, it is not invited, encouraged or vigorously protected.

Somewhat analogous to this situation is that in the broad area of self-directed economic provisionment, including such relatively unbusinesslike occupations as farming, and numerous handicraft trades, for example, painting and sewing. Here, too, competition is tolerated. But it is so far from being relied upon as a regulator of economic behavior that it is not only not encouraged; it is actively discouraged. By A.A.A. programs, soil conservation programs, coöperative marketing programs, and other measures, the government has undertaken to organize collective action and correspondingly to repress competitive effort in agriculture.[3] Similarly, in relation to handicraft trades, indeed in relation to labor employment generally, a governmental policy has developed of protecting, not competition, but voluntary concerted action. This is the essence of the National Labor Relations act, for example. In these spheres, it is true that while there may be formal statutory repudiation of the applicability of the antitrust laws (as by Section 6 of the Clayton act), some vestige of jurisdiction may still be retained thereunder by the courts. Even among farmers and carpenters, collective action that goes beyond mutual self-help and becomes predatory interference with others may be a restraint of trade. But where draw the line? In practice, even this negative element of antitrust jurisdiction is rapidly becoming a shadow without substance.[4] This is not offered as a criticism of the public policy in question. It represents merely a statement of fact.

[3] *Cf.*, Paul T. Homan, "Notes on Anti-Trust Policy," *Quart. Jour. Econ.*, Vol. 54 (1939), p. 73.

[4] See, *e.g.*, *Apex Hosiery Co.* v. *Leader*, 310 U.S. 469 (1940); *United States* v. *Hutcheson*, 312 U. S. 219 (1941); and *United States* v. *Brotherhood of Teamsters*, U.S. Supreme Court, October Term 1941, No. 131 and No. 132, decided March 2, 1942.

There is another large sector of economic behavior and relationships in which antitrust policy may be, one might say, theoretically applicable but in which it is not actually relied upon for the protection of public interests. This is the broad field of public utility services embracing such diverse industries as the railroads, with their enormous fixed capital investments, and radio stations, with little more capital requirements than that represented by a franchise to broadcast on "the air." In these branches of industry, whatever their distinctive economic characteristics may be—and this is a question which deserves more probing than it received either in the T.N.E.C. Hearings (9 out of 37 "parts") or in the supplementary monographs (2 out of 45 "studies") devoted to public utilities—competition is not sought or depended upon, in the main, to control prices, investment, output. A generalization of this kind is not very trustworthy, however. Whereas in the case of the railroads, rates may be rigorously regulated and yet competitive investment sanctioned and competition in service actively promoted and zealously protected, in the case of gas works or telephone systems, competitive investment and service may be forbidden, while in the case of banks, rates and services may not be regulated at all, or at least other than indirectly, though investment is meticulously controlled.[5] The incidence of these several variants of public economic policy in the public utility field, not simply upon the public utilities themselves and their immediate customers, but more especially upon the administration of the antitrust laws and their efficacy as instruments for the governance of trade and industry, deserves far more searching inquiry than it has received from the T.N.E.C. or its experts.

It is true that two special segments of such an inquiry as is here suggested were investigated by the T.N.E.C. These were the incidence of the investment policies and practices of insurance companies and of banking houses upon the capital market and indirectly, thus, upon the opportunities for free enterprise.[6] But even these investigations

[5] There are qualifications. Conciseness and accuracy make opposing demands. Traditionally, bank rates have been subject to usury laws, a nominal limitation. Recently rates *payable* on demand deposits have been subjected to regulation. *Minimum* (capital) investment is prescribed in some jurisdictions; and the effect of charter requirements may be to control in a measure the aggregate volume of investment in commercial banking. But the investment control to which reference is made in the text is primarily that of the *directions* of investment of bank funds, *i.e.*, the purposes for which, or the borrowers to which, loans may be made.

[6] See, in particular, Hearings, Pts. 10, 10A and 12, *Life Insurance;* and Pts. 22, 23 and 24, *Investment Banking.* The provocative *Study of Legal Reserve Life Insurance Companies* by Gerhard A. Gesell, T.N.E.C. monog. no. 28 [Washington, Supt. Docs., 1940], also considers this problem, but only incidentally. The primary emphasis is upon the issue of the consequences, for insurance safety and insurance cost, of the conditions and policies found.

were little more than exploratory. No intensive analysis was made of the potential hindrances and actual obstacles to the maintenance of effective competition in industry from the displacement (partly authoritative and partly contrived) and the perversion (wholly contrived) of competition in these two "businesses affected with a public interest." Beyond this, the T.N.E.C. did little more than scan the issues presented, for example, by the ownership or financial control of pipe lines (public utilities, at least nominally) by petroleum refiners;[7] and it left unprobed the challenging questions raised by the ownership of manufacturing concerns (*e.g.*, Western Electric) by public utilities (in this case, American Telephone and Telegraph), or by the joint ownership and/or control of manufacturing concerns and public utility enterprises, as in the case of the Pullman Company, or of the Aluminum Company of America. This is not to overlook, in the latter connection, the interesting and significant surveys of the wide-ranging interests of such fortune-building families as the Rockefellers, the du Ponts and the Mellons.[8] It is only to insist that the problem of coördinating variant policies of administrative regulation for public utilities with a policy of competitive-market regulation for numerous, diverse trades and industries—when the legal line of distinction seems to run tangentially or even haphazardly across any recognizable economic lines of distinction, and when financial integration recognizes no boundaries or distinctions whatever—is of an importance which has not yet been fully comprehended. It is hardly too much to say that the efficacy alike of administrative regulation of public utilities and of competitive-market regulation of most other lines of business hinges more immediately on the solution of this problem of reciprocal interference and mutual frustration than on almost any other single factor.

One other aspect of this somewhat neglected question of the interrelationship of public utility regulation and antitrust policy may be mentioned. That is the question of the treatment of patents. The position of patented inventions as a species of the genus public utility is not always, in fact is seldom, recognized. But a patent is a franchise,[9]

[7] The subject is discussed sporadically in the Hearings on the *Petroleum Industry*, Pts. 14, 14A and 15.

[8] See, especially, *The Distribution of Ownership in the 200 Largest Nonfinancial Corporations* by R. W. Goldsmith and others, monog. no. 29; and *Survey of Shareholdings in 1,710 Corporations with Securities Listed on a National Securities Exchange* by H. Granby and others, monog. no. 30. Several other monographs touch upon this matter, incidentally, also, *e.g.*, monog. no. 11 on *Bureaucracy and Trusteeship in Large Corporations;* and monog. no. 21 on *Competition and Monopoly in American Industry,* the first, in the course of a stimulating analytical study, the second, in a convenient compendium taxonomically embroidered.

[9] If legal authority be asked for a proposition which is so obvious in logic, it may be found in the following cases in which the Supreme Court has explicitly termed patent

and the possession of a franchise is the mark of a public utility.[10] Public utility regulation is intimately linked with, if it is not, indeed, derived from, the state's franchise-dispensing power. The essence of a franchise is not the privilege accorded to engage in a certain business. It is the restriction, expressed or implied, upon the freedom of others to enter the licensed field, in a word, to compete with the holder of the franchise, at will, and upon such terms as to these others may seem fitting. This is the gist of a patent. It takes out of the public domain a trade, a process, or a product which is, or otherwise would be, open to the public generally,[11] and gives exclusive rights therein to the inventor—actually, today, in practical effect, to his corporate employer. This is distinctly a special privilege.

The curious thing is that the grant of this particular type of franchise has not hitherto been attended with subjection to public regulation, as has the grant of other species of public utility franchises. Though a patent is in its very nature a *special* privilege, created and conferred by the government as a means of advancing what is deemed to be a *public* interest, and is thus logically indistinguishable from a franchise, for example, to broadcast on a specified wave length, for some incomprehensible reason it has continued to be treated, both by Congress and the courts, like property unaffected with a public interest. Whereas the manner of exercise of all other species of property affected with a public interest has long been recognized not only to be properly a matter of public concern but to require, on account of a peculiar susceptibility to abuse, special regulation, latterly reinforced by administrative supervision, the manner of exercise of patent franchises has continued to be regarded as nobody's business—except that of the patentee. And this policy has persisted notwithstanding the fact that the susceptibility to abuse arises in the one case as in the other from the same root cause, the monopolistic privileges conferred by the franchise. The obligation *to serve* the public, the obligation to render that

grants "franchises": *Bloomer* v. *McQuewan,* 14 Howard 539 (1852); *Chaffee* v. *Boston Belting Co.,* 22 Howard 223 (1859); *Seymour* v. *Osborne,* 11 Wall 516 (1870); *Mitchell* v. *Hawley,* 16 Wall 548 (1872).

[10] It is true that not every public utility enterprise may hold, as most of them do, a specific grant of public authority to engage in a given business within a given area upon given terms to the exclusion of certain others (not necessarily all others). There may still be some ferries, for example, which operate without benefit of a formal license or "certificate of public convenience and necessity." Such enterprises might be said to possess a "license by sufferance"; or perhaps the lawyers might find something akin to a common law franchise. In any event, such cases surely belong in what might be termed a marginal limbo.

[11] As stated by the Supreme Court in *United States* v. *Bell Telephone Company,* 128 U.S. 315,370 (1888), "The United States by issuing the patents which are here sought to be annulled has taken from the public rights of immense value and bestowed them upon the patentee . . . as an inclusive right."

service *without discrimination,* and the obligation to limit the charges for that service to *a fair return,* these elementary duties of a public franchise-holder which constitute in law and in reason the indispensable *quid pro quo* for the monopoly conferred by public authority, have all been ignored in the development, one might almost say the lack of development, of a public policy on the exercise of patent privileges.[12]

The consequences of this glaring anomaly, considered from the standpoint of its relation to the efficacy of antitrust policy, are only of late coming to be perceived. The T.N.E.C. has made an outstanding contribution to a better understanding of the deficiencies of public economic policy in the sphere of market regulation by focusing attention upon the pervasive and pernicious influence of the unregulated abuse of patent "rights" in undermining competitive conditions in industry. The facts brought out in the Hearings, Parts 2 and 5, regarding the influence of patent practices on the structure and functioning of the glass industry and the beryllium industry, and a few inadvertent disclosures in Part 3 of the Hearings regarding the restrictive operation of patent cross-licensing arrangements in the communications field, awakened a wide popular interest.[13] The conditions portrayed were so evidently a reflection of a prevalent conception in certain quarters of the business world that patent privileges in effect exempt patentees from the antitrust laws that the Department of Justice was moved shortly thereafter to institute a broad investigation of abuses of patent rights amenable to disciplinary action even without amendment of either the patent laws or the antitrust laws.[14] In the two years since that investigation was started a score of cases involving monopolistic restraints through the use of patents have been instituted, not counting all the separate actions, civil and criminal, founded on the same set of facts.[15]

[12] Compare: *Cotton Tie Co.* v. *Simmons,* 106 U.S. 89 (1882); *Second Paper Bag Case,* 210 U.S. 405 (1908); *Leeds and Catlin* v. *Victor,* 213 U.S. 325 (1909); and *General Picture Co.* v. *Western Electric Co.,* 304 U.S. 175 (1938), affirmed after reargument, 305 U.S. 124 (1938). These are only illustrative cases, exemplifying the worst aspects of our so-called "patent law."

[13] Hearings, Pt. 2, *Patents,* pp. 377-667; Hearings, Pt. 3, *Patents,* pp. 959-69 and 1001; Hearings, Pt. 5, *Monopolistic Practices in Industries, Development of the Beryllium Industry,* pp. 2011-2163. The facts presented in the Hearings on patents were developed through investigations conducted by the Department of Justice, under the direction of Mr. Joseph Borkin and Mr. Hugh Cox, who were commended by the committee for the excellent preparation and effective presentation of the material. Hearings, Pt. 5, *Monopolistic Practices in Industries, Development of the Beryllium Industry,* p. 2163.

[14] See Department of Justice, Press Release, "Investigation of Misuse of Patent Privileges," December 11, 1939.

[15] See U. S. Department of Justice, "*The Federal Antitrust Laws,* with Summary of Cases Instituted by the United States," Cumulative Supplements, March 15, 1941, August 1, 1941, and subsequent releases.

But while the T.N.E.C. Hearings provided some startling revelations on specific abuses of patent franchises, it remained for Professor Walton H. Hamilton in T.N.E.C. monograph no. 31, on *Patents and Free Enterprise,* to trace the sources and probe the implications of "the patent system" as it currently operates. The extent to which and the manner in which it has been perverted from a device for the promotion of advances in the industrial arts to a buttress of the vested interests of vast corporate estates is portrayed with extraordinary insight. Confusion, cross-purposes, and mutual frustration between antitrust and patent law are shown to have suffered the erection of utterly needless obstacles to free enterprise and effective competition which even a better implemented and more zealously prosecuted antitrust policy could scarcely have circumvented. Yet those two elements of public economic policy which have actually been permitted to develop antithetic tendencies clearly might have been so shaped that they would supplement and reinforce one another.

"A situation has blundered into being which calls for drastic amendment. A grant of privilege is conferred upon the inventor in order that the industrial arts may go forward. . . . The . . . 'exclusive right' of the inventor is a right—like all rights, subject to the general law—from which all other persons are excluded. The owners of patents attempt instead to make 'exclusive' mean absolute. . . . Repeatedly it has been argued that 'the patentee is Czar within his domain'; that 'he is under no obligation to deal fairly or obey the law' [quoted from brief for appellee, *Interstate Circuit* v. *U. S.*, 306 U. S. 208 (1939)]. . . . The grant of a patent is intended to protect an invention; in practice it repeatedly operates to block off a whole technology. . . . Thus it has come about that a patent is harnessed to causes it was never meant to serve. It may be used as a shield against public policy, as an immunity to the general law. . . . The net result is a strange anomaly within a democracy. An industry is removed from the control of the market and no substitute is provided for [the?] protection which has been forfeited. There emerges an industrial province completely independent of the authority of the Government. . . . If presently the patent is not brought into accord, free enterprise can survive only on the fringes of a closed economy."[16] The picture thus sketched is no surrealist distortion.

IV—Antitrust Procedure

Though the common law had long recognized a public interest in the processes of market adjustment, it had provided for that interest

[16] *Patents and Free Enterprise,* monog. no. 31, pp. 159-63.

no active, impartial champion.[17] Injuries sustained by private parties from certain types of restraints of trade might be redressed in civil actions for damages, and a restraint might so taint a transaction or relationship as to leave the parties thereto without a remedy for defection or for malfeasance *inter se se*. Perhaps the most distinctive features of the Sherman act of 1890 were the prohibition of privately contrived restraints of trade and the assumption by government of an obligation to discover, prosecute, and punish those who might presume thus to erect barriers to free opportunity in the market.

The policing of trade by public authority with the object of suppressing restraints was a new governmental function. Nevertheless, this novel responsibility was deemed sufficiently comparable to the traditional obligation of government to prosecute crimes against the common weal and to vindicate private rights which might be invaded that the use of the familiar, accredited techniques for law enforcement seemed warranted. Hence the technical devices provided for the implementation of antitrust policy were those suggested by experience. The prosecuting task was assigned to the Department of Justice with authority to proceed either by way of indictment or in equity; and the courts were authorized to entertain suits by those who might be "injured . . . in their business" by illegal restraints and, upon proper showing, to assess treble damages on the offending party. No special investigative body was set up, and no special investigative powers were conferred. No provision was made for official supervision of business practices and trade relationships, with or without regular reporting of their operations by those to whom the law applied. No standards were established for the privilege of engaging in interstate commerce in the corporate form of organization, or for the conduct of business in that sphere, apart from the injunction not to monopolize.

The reasons for the absence of legislative inventiveness, for the adoption of backward-looking procedural devices, are not far to seek. The policy the procedural devices were designed to enforce was itself backward-looking. It looked to the restoration of a pattern of industrial control which was visibly being wrenched, skewed, warped. The situation seemed to be getting out of hand, which is to say the competitive market was not functioning to provide adequate checks and balances among the various private interests which were supposed there, through enterprise, rivalry and bargaining, to reach equitable adjustment, economic equilibrium. The aim was to restore the full vigor of competition.

[17] See, on the deficiencies of the common law in this respect, the author's *Industrial Combinations and Public Policy* (Boston, 1927); *Trade Associations: Their Economic Significance and Legal Status* (New York, 1925); and his article on "The Economic Implications of Unfair Competition," *Iowa Law Review*, Vol. 21 (1936), p. 263.

The hope was that this might be accomplished simply by a minatory measure. In the middle of the most expansive era of American industry to have suggested that "trusts" and "malefactors of great wealth" were anything but adventitious excrescences on a sound body economic, might be symptoms of something more deep-seated, something in the nature of an arrested development of the forms of public control, would have been blasphemy. The theory of Antitrust was that if monopoly were roundly condemned, the occasional intervention of a vigilant public prosecutor backed by the might of majesty would be sufficient to discourage predatory aggression. The flow of investment funds, the output of goods, the movement of prices would proceed thus, unimpeded, in their accustomed channels and at their "natural" levels.

This defective implementation of antitrust policy from its inception has undoubtedly been a large factor in limiting its practical effectiveness. True, in the course of half a century there have been a number of developments, adaptations, and changes in the enforcement machinery originally provided. And in one instance, the establishment of the Federal Trade Commission in 1914, that machinery has been supplemented. Nevertheless, as Professor Hamilton makes clear in his excellent review of these developments in *Antitrust in Action* (monograph no. 16), the general pattern of enforcement procedure has remained essentially unaltered. It was not until 1903 that a separate division was created in the Department of Justice, especially charged with the enforcement of the antitrust laws. While this expedient has unquestionably greatly enhanced the efficiency and continuity of enforcement, it has not exempted the enforcement agency (1) from the binding influence of traditional conceptions and techniques so congenial to the legal fraternity, or (2) from the warping influence of political considerations flowing through a cabinet officer, subject, like his subordinates, to administrative pressure by the terms of this appointment. The establishment of the independent Bureau of Corporations in the same year and of its successor, the Federal Trade Commission, in 1914 provided additional facilities of investigation, and in the latter instance introduced an administrative procedure for the first time into competitive market regulation. But the narrowly circumscribed scope (unfair trade practices) of the administrative powers with reference to the general ambit of antitrust policy and the failure to integrate these auxiliary agencies of enforcement with the work of the Antitrust Division have limited severely the effectiveness of these gestures toward procedural supplementation.

The chief reliance, in fact, in the discharge of the primally important investigative function is still the cumbrous grand jury proceeding where-

in the Division becomes armed with the subpoena power. Thus equipped, and having enlisted the aid of a separate Justice bureau, the Federal Bureau of Investigation, whose operatives are primarily sleuths, trained in the technique and imbued with the traditions of the man hunt, the Division sallies forth to get its man—though the suspect is nowadays commonly a corporation, and the evidence sought relates not to low criminal hangouts and associations, but to business agreements and transactions of which a record or a clue may have been left in office files.

As Professor Hamilton emphasizes, the resort to criminal procedure puts enforcement upon a plane of combat in which the winning of a point through legal technicalities tends to overshadow the end of securing readjustments in business structure and policies which will effectuate the policy of the law. The real issues are prone to be confused and obscured. The negotiation of consent decrees has developed as one expedient for circumventing this handicap. It requires extreme caution and vigilance for effective use, but growing familiarity with the technique suggests that, in default of a more regularized and above-board procedure in which jurisdiction is formally acknowledged and assurance is provided that all cards are placed on the table, it may become a fairly dependable instrument of regulation. But it will always remain a makeshift, bearing the marks of its origin in improvisation.

Of the two civil remedies now open to the government, one, that by way of an action *in rem* for forfeiture of goods in transit, provides so light a penalty and affords such a limited opportunity for effective preparation of the government's "case," that it has seldom been invoked.[18] The other, that by way of a suit in equity for an injunction, is of far more practical value than the first but is subject to serious limitations also. Two of these only will be noted here. First, it affords no means whereby the Department can secure evidence on an other than voluntary or "negotiated" basis. Secondly, the penalties it provides have little deterrent effect since they do not directly penalize officers and directors and since they amount to no more than a requirement of abandonment of objectionable practices or, in the case of dissolution, restoration of the *status quo ante*—usually in part only!

By way of supplement to the existing procedural devices available for antitrust enforcement, it has been proposed that additional civil remedies be accorded the government. These might or might not be of similar character and scope to those now provided by Section 7 of the

[18] Seizure of goods in transit presupposes a clear violation of the statutes by the offending shipper. Where the violation can be readily established, as by a simple examination of the goods (*cf.*, Food, Drugs and Cosmetics act offenses), this may be an appropriate remedy. But it is quite ill-adapted to antitrust law enforcement, since the proof of an offense involves an arduous time-consuming task in assembling the necessary evidence.

Antitrust act in favor of private parties.[19] The T.N.E.C. recommended that they should not be so limited, but should afford a basis for recovery of "forfeits," independently of proof of "damages."[20] In the bill introduced by Senator O'Mahoney[21] in furtherance of this recommendation, it is provided that directors and officers of an offending corporation shall be liable to the government for twice the amount of compensation received by them from the corporation during the continuance of an illegal restraint or "attempt to monopolize." In addition, an offending corporation is itself made liable, in a civil suit, for twice the amount of net income earned by it during the period of antitrust law violation. These additional remedies, if granted, should go far to enhance the respect for the law among business men and increase the efficacy of enforcement.

No attempt will be made here to trace the varying fortunes of Antitrust through the permutations of political administration, through prosperity and depression, through hot and cold seasons of the climate of judicial opinion, through alternations in administrative preference for one or another of the available procedures, formal or informal, lionlike or lamblike. All this has been done so admirably in Professor Hamilton's

[19] Proceeding without supplementary legislation, the government, in its first and only attempt to secure relief via Section 7, was defeated. *U. S.* v. *Cooper Corp.*, 312 U. S. 600 (1941). But it may be doubted that even had it obtained a construction of Section 7, or should it obtain a statutory authorization, enabling it to sue for and recover damages, as private parties may now do when "injured" by a violation of the law, this would reinforce its procedural armory appreciably.

While it has been decided [*Connolly* v. *Union Pipe Co.*, 184 U. S. 540 (1902); *cf.*, *Wilder* v. *Corn Products Refining Co.*, 236 U. S. 165 (1912)] that it is not an adequate defense, in a suit for the recovery of the purchase price of goods delivered, to set up that the seller is engaged in an illegal restraint of trade or constitutes a monopoly, apparently it has never been decided that a buyer who pays the agreed purchase price to a seller monopolizing the article sold may not maintain an action for treble damages, under Section 7, on account of the "injury" sustained by him "in his business" by having had to pay an "excessive," or at any rate a noncompetitive, price. But since the great majority of the cases [see *Wheeler-Stenzel Co.* v. *Glass Jobbers Assn.*, 152 Fed. 864 (1907); *Van Camp* v. *American Can Co.*, 278 U. S. 245 (1929); *Story* v. *Paterson Paper Co.*, 282 U. S. 555 (1931), and cases there cited] in which private litigants have succeeded in recovering treble damages under Section 7 have involved either aggressive, predatory interference with, or discrimination against, the plaintiff's business by the defendant—and not simply a sale of merchandise to the plaintiff at a monopolistically elevated price—if the new civil remedy proposed were no more than an extension to the government of the right of action now accorded private persons by Section 7, it would probably avail the government little. For it may be presumed that few, if any, concerns engaged in violating the antitrust laws, whether by conspiracy or otherwise, are involved in a species of Guy Fawkes conspiracy to "put the government out of business," or hamper it in the conduct of public business.

[20] In a Preliminary Report to Congress, dated July 14, 1939. See *Final Report and Recommendations to the T.N.E.C.*, S. Doc. No. 35 (77th Cong., 1st sess.), p. 40.

[21] S. 2719 (76th Cong., 1st sess.), introduced June 29, 1939. In a statement by Senator O'Mahoney accompanying the submission of the bill, the coöperation of Assistant Attorney General Arnold in drafting it is acknowledged. *Congressional Record*, Vol. 84, p. 8192.

monograph that it would be superfluous again to go over the ground. It suffices to state that the conclusion he reaches that the institution of an administrative process, with the grant (evidently) of wide discretionary powers to the administrative agency, offers the most promising solution to the perplexing problem of enforcement of antitrust policy. The suggestion is frankly based on experience, chiefly in governmental regulation of public utilities.

Without attempting here an exhaustive analysis of the issues raised by this proposal, certain grounds for reservation of judgment on its efficacy and adequacy may be mentioned. (1) Experience in public utility regulation has not been unqualifiedly gratifying;[22] nor does the record of administrative regulation of trade practices by the Federal Trade Commission serve to generate much confidence in an expanded use of the device.[23] (2) There are some distinctive economic characteristics of public utilities, even though these have not always been clearly discerned, definitely formulated, and officially respected.[24] (3) Public utility regulation has been adopted in response to pressing exigencies in particular industrial situations and proceeds, in theory at least, in accordance with specified standards prescribed by the legislature. In contrast, under the instant proposal the administrative jurisdiction would be economy-wide and the range of administrative discretion in defining standards and determining what industries would be subject to one standard and what to another would apparently be unconfined. Not all the forebodings of bureaucracy are fanciful.[25] Finally, for present purposes, (4) the proposal leaves untouched the fundamental issues concerning the patterns and standards of enterprise organization, of the relationships of various interests in the corporate units in which eco-

[22] *Cf.*, Federal Communications Commission, *Proposed Report on Telephone Investigation,* pursuant to Pub. Res. 8, 74th Cong. (Feb. 23, 1938); N.Y. Legislature, *Report of the Joint Legislative Committee to Investigate Public Utilities,* Albany (Feb. 12, 1935).

[23] See Myron W. Watkins, *Public Regulation of Competitive Practices* (3rd ed.; New York, 1940); also, the writer's review of the Federal Trade Commission's *Control of Unfair Competitive Practices through Trade Practice Conference Procedure,* monog. no. 34, in *Am. Econ. Rev.,* Vol. XXI (Dec., 1941), p. 845.

Significantly, Professor Hamilton makes no attempt to relate his proposed administrative agency to the F.T.C., or to base its promise on the latter's record.

[24] See, in this connection, Professor W. L. Crum's penetrating criticism of Mr. Gardiner Means's tendency to minimize the significance of these distinctions in his analyses of financial concentration: W. L. Crum, *Corporate Size and Earning Power* (Cambridge, 1939). For a brief summary of the economic characteristics of public utilities, see the writer's "Economic Prospects of Air Transport," *Pub. Utility Fortnightly,* Vol. IV, No. 6 (Sept. 19, 1929), p. 332. A more extended essay on the same subject is *Economic Basis of Public Interest,* by Rexford G. Tugwell (Menasha, 1922).

[25] See Robert Brady, *The Rationalization Movement in German Industry* (Berkeley, 1933); and the same author's *The Spirit and Structure of German Fascism* (New York, 1937).

nomic activities are actually carried on. It either ignores or, on occasion, accepts as inevitable the prevalent oligarchic organization of industry and attendant oligopolistic market conditions.[26] Can an antitrust policy worthy of the name thus make peace with "monopolistic competition"? Would a "negotiated peace" in this field have any better prospect of enduring than a settlement in that fashion of the parallel conflict between freedom and authority in the political sphere, now being waged on the battlefields?

V—An Attempt at Appraisal

Not all of the shortcomings of antitrust policy in respect to the preservation of vigorous competition and the effectuation of a democratic control of industry are traceable to defective implementation. True, the Antitrust Division has been severely hampered in the attempt to police the whole range of American industry on an annual budget which never exceeded $300,000 prior to 1936 and is even today less than 75 per cent of that of the Railroad Retirement Board! But inadequate appropria-

[26] That such a premise or implication is not logically unavoidable in the advocacy of an administrative set-up which would exercise regulatory powers industry-by-industry in accordance with its own discretion may be conceded. But it is none the less true that in practice the advocacy of such a policy and the acceptance of the conditions described go hand in hand. This was made clear in Professor Hamilton's case, for instance, on the occasion of one of his earliest public espousals of the program in question. See, Milton Handler (ed.), *The Federal Anti-Trust Laws: A Symposium* (Chicago, 1932), which started somewhat of a "feud" on this issue between Professor Hamilton and Professor Frank A. Fetter.

The issue came to the surface in the course of Professor Fetter's testimony on March 8, 1939, particularly in connection with his interrogation by Mr. Jerome Frank. (Hearings, Pt. 5, *Monopolistic Practices,* pp. 1951-82.) Mr. Frank took as the point of departure for his questioning, Exhibit no. 358 (*ibid.,* pp. 2192-2200) a statement prepared by the Federal Trade Commission with which the S.E.C. Commissioner seems to have disagreed sharply.

Mr. Frank's position may be indicated by a brief quotation (p. 1959): "It seems to me that what we need to do is to canvass the possibilities of working, in some industries, with a minimum of the drastic, iron-handed governmental imposition that the word 'regulation' connotes, and see whether we cannot work, *perhaps with some modicum of law*—with a greater quantity of legal apparatus in some industries and less in others—to get the desired end." (Italics supplied.)

Professor Fetter's position may likewise be indicated by a brief excerpt from his testimony (p. 1981), though in both cases a single extract from a long discussion does less than justice to the parties. Responding to a summary of Mr. Frank's suggestion by Mr. Berge, he stated: "If we go far with that thought we are going to have a bureaucratic examination and regulation of each separate industry, whereas I think the N.R.A. is an example of the fact that if there were any regulations of ethical practice that were valid for one industry they were probably valid for all. The notion that you would have a separate ethical code for each one of five or six hundred industries is an absurdity." (The "ethical" adjective might be dropped without misrepresenting Professor Fetter's thought, it is believed.)

This basic issue persists. The Hamilton-Frank thesis is sharply challenged, *e.g.,* in a recent article by Corwin Edwards, "Economic Implications of Business Boundary Laws," *Law and Contemporary Problems,* Vol. VIII, No. 2 (1941), p. 292.

tions and blunt procedural tools are not alone responsible for Antitrust's failure to forefend that concentration of economic power which called the T.N.E.C. into being.

Aside from its diminutive size and poor equipment measured against the mounting scale of the task confronting it, the Division has been charged with the enforcement of a policy which has not always been what it seemed. If the antitrust act was a product of its times, antitrust policy has equally been a product of changing conditions and changing conceptions of what the public interest required. These shifts in the concrete meaning of antitrust policy have in part proceeded from modifications of the outlook and aim of succeeding administrations, as noted above. Perhaps to an even greater extent, however, they reflect shifts in judicial opinion and in legislative policy.

To consider the former influence first, the course of adjudication has in some respects been not only singularly tortuous but markedly obstructive from the standpoint of effectuation of the policy of the law. One, but only one, of the impediments thus put in the way of effective antitrust enforcement is that emphasized by Professor Handler in his *Study of the Construction and Enforcement of the Federal Antitrust Laws* (monograph no. 38). It is the difficulty of extracting from the series of antitrust decisions, and still more from the succession of rationalizing opinions, any definite, dependable criteria of the essential elements of illegality. What part, if any, of the source of this difficulty resides in a judicial, and judicious, hesitancy to make definitive commitments, a timid inclination to hide behind the skirts of the rule of reason, and what part in a deliberate choice of the devious paths of expediency in preference to the straight and narrow road of principle is not clear.

Whatever the explanation, Professor Handler's study conclusively demonstrates that an effort to discover consistency and continuity in the antitrust decisions is foredoomed to futility. The difficulty is not only in reconciling the trend of judicial opinion in cases involving collusive action with that in cases concerning proprietary fusion or monopolistic practices independently framed and followed.[27] The logician must go to some pains to eliminate any trace of conflict between such confederative cases at those of the Window Glass Manufacturers,[28] and Appalachian Coals,[29] on the one hand, and of Trenton Potteries,[30]

[27] *Cf.*, *e.g.*, as did Mr. Justice Brandeis, in dissent, the judgment in the *Harwood* case, 257 U.S. 377 (1921), with the decision in the *Steel* case, 251 U.S. 417 (1920). Or, again, compare the verdict in the *Gasoline Buying Pool* case, 310 U.S. 150 (1940), with the judgment in *General Talking Pictures Co.* v. *Western Electric Co.*, 304 U.S. 175, 305 U.S. 124 (1938).

[28] 263 U.S. 403 (1923).

[30] 273 U.S. 392 (1927).

Sugar Institute,[31] and the Gasoline Buying Pool,[32] on the other. On the status of mergers, it would tax the ingenuity of even the most gifted artist in legal legerdemain to bring into accord the series of decisions running from the Knight case through the Northern Securities, American Tobacco, Standard Oil, Shoe Machinery, and Steel cases to the recent Aluminum decision.[33] The tergiversations of judicial opinion in interpreting the law have surely been a considerable factor in limiting the achievements of Antitrust.

But this is not all. A far more formidable obstruction from this quarter to the effectuation of the policy of the law, if that be taken as the maintenance of genuinely competitive markets, has been the indifference displayed by the courts, in applying the standard established by Congress, to the significance of what may now be termed "conditions of monopolistic competition." Without benefit of economic training, unskilled in economic analysis, and disdaining economic advice,[34] the courts have developed, particularly in applying the rule of reason to mergers, a tolerance of oligopoly which is incompatible with the preservation of forthright competition in the market.[35] The simple fact is that where sellers are few neither collusion nor oppressive tactics are required to stifle competition. No legal casuistry can eliminate the pressure toward price stabilization resulting from canny attention to the marginal revenue curve. No glib phrase making "size . . . no offense" can dispel the telltale evidence of restraint in identical bids,[36] simul-

taneous price changes,[37] uniform delivered prices,[38] and sustained price differentials in domestic and export trade,[39] or in sales of the same products for different uses or to different classes of customers.[40]

Nor have Congress and the state legislatures evinced a steadfast determination to uphold antitrust policy. They have not hesitated in deference to the clamor of special interests to grant exemptions, suspensions, and modifications which could not fail to have an obstructive, in some cases a virtually emasculative, effect upon antitrust policy. Since 1914 the trend of federal regulatory legislation is indicated by such statutes as the Shipping act of 1916 as amended by the Merchant Marine acts of 1920, 1928 and 1936,[41] the Webb-Pomerene act of 1918,[42] the Fishing Industry act of 1934,[43] the Bituminous Coal Conservation act of 1935 and its successor, the Bituminous Coal act of 1937,[44] the Robinson-Patman amendment,[45] and the Miller-Tydings amendment.[46] In addition to the foregoing legislation, there is a long list of federal statutes granting virtual exemption from the antitrust laws to agriculture,[47] and the National Industrial Recovery act

Reeside, *Price Discrimination in Steel,* monog. no. 41; Federal Trade Commission, *The Basing Point Problem,* monog. no. 42; and R. C. Cook, *Control of the Petroleum Industry by Major Oil Companies,* monog. no. 39, pp. 43-44, 48.

[39] See M. Gilbert and P. D. Dickens, *Export Prices and Export Cartels,* monog. no. 6, pp. 74-81.

[40] See S. Nelson and W. G. Keim, *op. cit.,* pp. 80 *ff.,* C. L. James, *et al., Industrial Concentration and Tariffs,* monog. no. 10, *passim, e.g.,* gypsum, p. 39, and plate glass, p. 51; and D. Bertrand, *et al., The Motion Picture Industry—A Pattern of Control,* monog. no. 43, p. 43, *et passim.* See also Brief for the United States in *U.S.* v. *Aluminum Co. of America, cit. supra.*

On the significance of price discrimination in relation to market control, compare J. M. Clark, *Studies in the Economics of Overhead Costs* (Chicago, 1923) chap. 20, and the writer's article on "Price Discrimination" in the *Encyclopedia of the Social Sciences,* Vol. XII, pp. 350-55. While it may be true that sporadic, irregular discriminations may signalize a sort of surreptitious competition in an otherwise monopolistic market, sustained discriminations are hardly compatible with free competition. They are an infallible index of monopoly.

of 1933-35 providing generally for an interlude in antitrust enforcement.[48] Nor can one afford to overlook in this connection the headlong, if not heedless, rush of the several states latterly, not only to follow the lead of Congress, but to outdo it—and each other—in sanctioning trade restraints and fettering competitive forces.[49] The cumulative influence of these developments has been a factor of no small moment in frustrating the efforts of Antitrust to effectuate the policy of the law.

It is plain that in the foregoing circumstances, at least, antitrust policy has not met the pragmatic test. The tendency toward concentration of economic power has not been arrested. In some spheres a feudal hegemony has been established and maintained seemingly without challenge, as in sulphur, bearing metals, borax, molybdenum, oxyacetylene, plastics, plate glass, and gypsum.[50] In others, it has developed and persisted despite sporadic and ineffectual efforts to curb manifest restraints, as in steel, tin cans, refractories, cement, aluminum, copper, sugar, nitrogen, radio, motion pictures. In still others domination of the market has survived repeated prosecutions and frequent adverse decrees as in oil, tobacco, lumber, anthracite coal, meat packing, office equipment, and photographic supplies.[51] On the other hand, there

Sugar Production and Control act of 1937, as amended, U.S. Code, Title 7, chap. 34.

[48] Act of June 16, 1933, U.S. Code, Title 15, chap. 15, secs. 701-12. Certain provisions were declared unconstitutional in *Schechter Poultry Corp.* v. *U.S.*, 295 U.S. 475 (1935). Compare: L. S. Lyon and others, *National Recovery Administration* (Washington, 1935), and President's Committee of Industrial Analysis, *Final Report* (Washington, 1937), 75th Cong., 1st sess., H. Doc. 158.

[49] Some 45 states now have so-called "fair trade" statutes validating resale price maintenance. See Commerce Clearing House, *Trade Regulation Service*, Vol. II, p. 10001. And 31 states forbid sales below cost and/or similar "unfair practices." *Ibid.*, p. 9002. In addition, numerous states have enacted discriminatory chain-store tax legislation, business boundary laws (limiting the lines of trade in which particular enterprises may engage or types of service they may render), and a wide variety of other measures designed to preserve or advance the interests of local trade or special groups. See "Symposium on Governmental Marketing Barriers," *Law and Contemporary Problems*, Vol. VIII, No. 2 (1941).

These developments were sharply criticized by numerous witnesses in the Hearings, Pt. 29, *Interstate Trade Barriers*. In the monographs they received less attention, and the tone of the treatment was in general more explanatory and less censorious. Compare, J. H. Cover *et al.*, *Problems of Small Business*, monog. no. 17, and B. W. Lewis *et al.*, *Economic Standards of Governmental Price Control*, monog. no. 32, Pts. 2 and 4.

[50] These and other industries listed below are selected at random from those discussed in the Hearings and monographs. The most comprehensive survey, but not the most penetrating and incisive study, of the structural features of industry among the T.N.E.C. monographs is Clair Wilcox's *Competition and Monopoly in American Industry*, monog. no. 21.

[51] It is not to be inferred, of course, that judgments adverse to defendants, whether or not accompanied by dissolution decrees, have had (1) no effect whatever in relation to market control, or (2) the same effect in every instance cited. The detailed analysis of the

are familiar examples, like bituminous coal, cotton textiles, leather, rubber, and shoes, of industries in which competition may be unrestricted, perhaps too severe, but in which in any case the adjustments of supply and demand, the composition of private interests, are not invariably smooth and economically advantageous. Still other industries conform to none of these patterns. The whole range of trades serving essentially local markets may be here tied up in vice-like restraints, there flexibly competitive, elsewhere conducted in a sanguinary rivalry that leaves ruin—or racketeering—in its wake.

Manifestly the diffusion of industrial control at which the Antitrust act aimed has not been realized. The spontaneous assertion of diverse private interests, each accommodating itself to the demands of opposing interests with a minimum of friction, and all held in check within decorous limits by the occasional intervention of Antitrust to admonish an overzealous aggressor or reprove a misguided conspirator, remains a remote ideal. With the years the mobilization of industrial resources, human and material, into ever larger aggregates, with attendant concentration of economic power, has proceeded, not unchecked, but despite the law and administration of Antitrust. New and subtle restraints, perhaps operating in the guise of statistical exchanges, basing point systems, standardization programs, or estimate bureaus, have displaced the old piratical practices and gentlemen's agreements which entailed too much risk of public obloquy and legal penalty. In the corporate labyrinths of big business, management has become further and further divorced from ownership and in its consequent irresponsibility has been enabled to provide amply for its own "social security." Wage-earners have lost much of their independence. They produce, perforce, what they are told to produce, in the way they are told to do it, humbly grateful for the opportunity which a job affords, when one happens to be available, bitterly resentful of the implications of a discharge which comes through no fault of theirs. Consumers may not admit their resemblance to guinea pigs, but, powerless to escape the ubiquitous promptings of advertisement, they find resistance to its appeals an industry of diminishing returns.[52]

changing patterns of control in these industries, and others which might be added, is clearly beyond the compass of the present paper. It requires, indeed, a whole book to make a satisfactory study of even a single branch of, for example, the chemical industries as Professor T. J. Kreps discovered, or at any rate demonstrated, in his work on *The Economics of the Sulphuric Acid Industry*.

Nevertheless, generalizations cannot be avoided altogether if any constructive use is to be made of experience in formulating policy. If the specific generalizations here made were challenged, the answer would be an appeal to the T.N.E.C. record—and, if need be, to whatever data outside that record might be available.

[52] By and large, adequate substitutes for a product appear to be available approximately in inverse proportion to the extent that the claims of its excellence are, may one say, exaggerated. This is hardly a coincidence.

But if Antitrust were implemented with sharper tools and provided with ample resources; if the unwonted vigilance and energy recently displayed in the execution of its police assignment could be sustained; if a better coördination of antitrust policy with other regulatory policies and a more consistent adherence thereto by the lawmakers could be assured; and finally if more definite criteria were developed and more unflinchingly applied by the judiciary—what then? Would Antitrust suffice? Could these more favorable conditions be assured? No one can answer these questions with certainty. But it may be doubted that even if antitrust policy were wholeheartedly supported and firmly enforced by the legislatures, the courts, and the administrative agencies it could, by itself, restore or insure a competition at once forthright and salutary in modern markets.[53] The grounds for that doubt are spread upon the records of the T.N.E.C., through 82 volumes of testimony and reports.

The trouble lies deeper than in mere market-manipulating schemes. It lies in the forms of organization and the mode of functioning of business enterprise itself, from which competitive forces spring or in which they are stifled. Year by year the control of industry has become more of a special privilege. In the corporate units of business enterprise, the interests of investors, the interests of workers, the interests of consumers have been subordinated to the quest of inside cliques for power, prestige, and profits (pelf might be a better word).[54] It is a commonplace that management has been divorced from ownership. The fact is, it has in large measure been divorced from responsibility, and therewith, and to that extent, spontaneous enterprise has been extinguished and competitive forces devitalized. The erratic operation of industries subject to such irresponsible management, with a pattern of control so unbalanced, cannot indefinitely be suffered. Antitrust is not enough.

But Antitrust was never put forward as an ultimate solution of the perennial issue of public policy. It represented no more than an initial step. And it was a beginning in the right direction. It was an assertion that the public interest in the conduct of industry is paramount to any private interest. This was a gesture that needs no apology, a step that

[53] *Cf.*, Corwin D. Edwards, "Can the Antitrust Laws Preserve Competition?" *Amer. Econ. Rev.*, Suppl., Vol. XXX (1940), p. 164.

[54] "The proof of the pudding" is in the exigent circumstances which have constrained the three vital economic interests subordinated to business interests to seek, and a democratic government to grant, each in turn special administrative protection. The S.E.C. was established to safeguard the interests of investors who, in the current organization of industrial control, found themselves disfranchised and defenseless. Likewise, the N.L.R.B. was set up as a means of protection of the interests of labor and the F.T.C. (and several other administrative agencies, such as the Food, Drugs and Cosmetics Administration) in defense of consumer interests.

needs no retracing. It is true that Antitrust has essentially a negative thrust. It can, on occasion, eradicate restraints privately laid on an industry, forbid surreptitious toll-taking on the channels of trade. It has no power to initiate realignments in the structure of an industry which may promise enhanced efficiency, no authority to cultivate new trade practices, selling policies, or investment programs which might stabilize a distraught industry. Above all, it has no mandate to establish standards for the organization of the corporate units of business enterprise which will insure their responsible management, their healthy functioning as the very cells of the body economic. As a licensed physician to the economy, it is limited to the practice of surgery. Fifty years ago preventive medicine was regarded by robust men as vapid quackery. Times change.

Comes the emergency! If Antitrust is not enough, some would say let us scrap it, or at the least let us shelve it, as in 1933. If monopolistic competition, restrictive devices, privately administered prices are so prevalent that, before Antitrust can fulfill its appointed function and provide reasonably adequate defense of minority groups, inarticulate interests, incipient enterprise, the whole structure of industry must be rebuilt, decentralized, perhaps reorganized on coöperative lines, that is too large a task to undertake now, we are told. In so far we are well advised. Wartime pressures, anxieties, fears are not conducive to an amicable reconstruction of the bases of industrial control which in any event must involve some sacrifice of vested interests, considerable tutelage in new responsibilities, and groping accommodation to altered relationships.

But it does not follow from the admission that Antitrust is not enough that it can safely and advantageously be suspended, even in a time of crisis. What a national defense program or a war production program undoubtedly requires is the mobilization, coördination, and direction of industry as a unit. With the issuance and enforcement of government *orders* that this shall be done and that shall not be done, Antitrust has no quarrel and in no wise interferes. But with privately contrived stratagems involving mutually imposed restraints of trade, either beyond the scope of the governmental orders or designed to influence their terms, Antitrust does interfere.[55] Signs are not wanting today that, if vigilant efforts to free the economy of "voluntary" restraints unwarrantedly imposed for the benefit of special interests were abandoned, the experience of 1917-18 and of 1933-35 would be repeated.[56] For the protection of the public interest, which government

[55] See *Annual Report* of Assistant Attorney General Thurman Arnold, in charge of Antitrust Division, for the year ending June 30, 1941.

[56] Detailed studies of specific industries reveal beyond shadow of doubt that expansion

was constituted to safeguard and promote, can reliance be placed upon the patriotic animus and dollar-a-year self-immolation of special interests?

Antitrust is not enough, true. But at least it sets some limits to predacious actions. It cannot assure forthright competition (even if that were everywhere desirable), but it can and does provide a leverage for the promotion of adjustments (in prices, output, investment) toward the competitive standard of full utilization of resources. By freeing industry, in some measure, of the obstructions which have been, and constantly are being, fastened upon it by lopsided patterns of control (undue concentration in private hands of discretionary economic power), its effective contribution to national defense will be by so much advanced. Even more important, by the assurance given a people by its government through a vigorous policy of antitrust enforcement that it is earnestly bent upon making industry an instrument of the common welfare, not a means to the brazen aggrandizement of some special interest, it will fortify their spirit and seal their loyalty for the hard tests which lie ahead. For, after all, support of Antitrust is a pledge of good faith in the avowed devotion to a democratic way of life. No government which is itself founded on the principle of consent of the governed can afford to retreat from that principle in its policy with respect to the control of industry.

For the long run—what then? If this be for the night, "Watchman, what of the morrow?" When the reconstruction of the government of industry upon a genuinely democratic basis can be safely essayed, what shall the model be? Assuming that the Fates grant us that privilege, but without pretension to a foresight adequate to anticipate what the complexion or balance of economic forces may then be, this alone may be ventured. If the goal be accepted of a wide diffusion of industrial control, of a democratic sharing in the responsibilities of industrial government, it will not be achieved by reform from top to bottom. It will come only through reconstruction from the bottom up. So long as the irresponsible management of giant corporations persists, the attempt to preserve competition in the markets through a policy of admonishing the custodians of this privilege to be "good" and not "restrain trade,"

of production of materials vitally necessary for the conduct of the war is in many instances, even now, being geared to military requirements only to the extent that provision of these requirements is compatible with a cautious estimate of the profit-making prospects of expanded facilities. The root cause of these tactics is plain: the reluctance of interested parties to relinquish the restrictive devices or relax the restrictive policies upon which monopolistic gains depend.

"Antitrust investigations during the past year have shown that there is not an organized basic industry in the United States which has not been restricting production by some device or other in order to avoid what they call 'ruinous over-production after the war.'" From *Annual Report* of Assistant Attorney General Thurman Arnold (1941), p. 1.

which is to say through antitrust policy as it stands today, will fall short of the goal.

The *sine qua non* for an effective assertion of the public interest in the conduct of business is the establishment, or if you prefer the re-establishment, of responsible management. That can only be done through a reorganization of the corporate units of enterprise in such fashion that the vital economic interests now disfranchised shall be represented in the councils where, in the first instance, decisions are made, policies formed, operating results determined, and management obliged periodically to account. Such a reorganization can be affected only through federal incorporation.[57] Competition in franchise-granting among the states, their so-called charter-mongering, is incompatible with the erection and maintenance of salutary standards of managerial responsibility.

It is the failure to recognize this basic fact and to appreciate its implications which accounts, one must suppose, for the timidity and temporizing which mark the conclusions of what might have been one of the most significant studies among the T.N.E.C. monographs. The authors of *Bureaucracy and Trusteeship in Large Corporations* (monograph no. 11) find ample grounds for criticism of the manner in which self-perpetuating and self-serving managements have perverted the functions of enterprise. But their conception of how this perversion may be abated is singularly naïve. They would trust to the voluntary acceptance of fiduciary obligations by autocratic managements shorn of none of their privileges, this acceptance to be won somehow through the pleadings and "expectations" of the patient public. The only alternative to "trusteeship" which they envisage is the imposition of "additional control over management" by government.[58] In these circumstances they are apprehensive, and justly so, that "regulation may defeat its own purpose. . . . However, it might be of substantial assistance if some governmental body, such as the Temporary National Economic Committee, would deplore the present tendency. . . . It may not be necessary to enact legislation. . . . We suggest that less drastic means should first be tried. Well-thought-out advice and publicity, for example. . . . A widespread, favorable attitude of mind is a first essential to effective

[57] See the writer's memorandum in *Relative Efficiency of Large, Medium-Sized and Small Business*, monog. no. 13, Appendix A.

[58] Presumably this means a public utility type of regulation. *Bureaucracy and Trusteeship in Large Corporations*, monog. no. 11, p. 123. There is no implication in the discussion in the text above of criticism or derision of the concept of trusteeship *per se*. In fact, a decade ago the writer supported, as he would still support, the development of intra-corporate trustee relationships. See his "Trustification and Economic Theory," *Am. Econ. Rev.*, Suppl., Vol. XXI (March, 1931) p. 54. But it is one thing to impose and enforce fiduciary obligations; it is quite another matter to trust to the slow emergence of quasi-professional standards among business executives.

trusteeship in big business. People must expect and assume that managers will look out for interests other than their own. Managers in their turn will then attempt to live up to expectations."[59]

Such faith may be sublime—or puerile. Whichever it is, not cynics alone will be skeptical of its adequacy to sustain popular patience and good will pending its realization. Realists, too, will have their reservations. It is encouraging to find among those who appreciate the imperative need of supplementing Antitrust, by restoring industry to responsible management, if its wholesome ends are to be achieved, no less a realist than the chairman of the Temporary National Economic Committee itself. His Final Statement is after the model of the President's letter which initiated the inquiry: lucid yet compact, impartial yet discriminative.

> The first and most necessary step is to recognize that we must have a national rule for national business. . . . If we desire to have business carried on by collective units, and it must be carried on thus in the modern world, then we must find the way to make these units thoroughly democratic. Economic freedom and political freedom go hand in hand. Neither can survive without the other, and since . . . in a republic the government of all the people must be able to speak for all the people . . . we have no recourse except to have that government define the rights, duties and responsibilities of the organized agencies which conduct and control the commerce on which its citizens depend for employment and income.
>
> It is idle to think that the huge collective institutions which carry on our modern business can continue to operate without more definite responsibility to all the people of the Nation than they now have. To do this it will be necessary, in my judgment, to have a national charter system for all national corporations.[60]

For those who have not succumbed to stark cynicism from contemplating or experiencing our last two "reconstruction periods," in this evidence of economic statesmanship triumphant over political poltroonery may be found a ray of hope to sustain them through the trials that now beset us, and the still greater trials that lie ahead.[61]

APPENDIX A

MESSAGE FROM THE PRESIDENT OF THE UNITED STATES TRANSMITTING RECOMMENDATIONS RELATIVE TO THE STRENGTHENING AND ENFORCEMENT OF ANTI-TRUST LAWS[1]

To the Congress of the United States:

Unhappy events abroad have retaught us two simple truths about the liberty of a democratic people.

The first truth is that the liberty of a democracy is not safe if the people tolerate the growth of private power to a point where it becomes stronger than their democratic state itself. That, in its essence, is fascism—ownership of government by an individual, by a group, or by any other controlling private power.

The second truth is that the liberty of a democracy is not safe if its business system does not provide employment and produce and distribute goods in such a way as to sustain an acceptable standard of living.

Both lessons hit home.

Among us today a concentration of private power without equal in history is growing.

This concentration is seriously impairing the economic effectiveness of private enterprise as a way of providing employment for labor and capital and as a way of assuring a more equitable distribution of income and earnings among the people of the Nation as a whole.

I. The Growing Concentration of Economic Power

Statistics of the Bureau of Internal Revenue reveal the following amazing figures for 1935:

"Ownership of corporate assets: Of all corporations reporting from every part of the Nation, one-tenth of 1 per cent of them owned 52 per cent of the assets of all of them.

"And to clinch the point: Of all corporations reporting, less than 5 per cent of them owned 87 per cent of all the assets of all of them.

"Income and profits of corporations: Of all the corporations reporting from every part of the country, one-tenth of 1 per cent of them earned 50 per cent of the net income of all of them.

"And to clinch the point: Of all the manufacturing corporations reporting, less than 4 per cent of them earned 84 per cent of all the net profits of all of them."

The statistical history of modern times proves that in times of depression concentration of business speeds up. Bigger business then has larger opportunity to grow still bigger at the expense of smaller competitors who are weakened by financial adversity.

The danger of this centralization in a handful of huge corporations is not reduced or eliminated, as is sometimes urged, by the wide public distribution

[1] S. Doc. No. 173, 75th Cong., 3rd. sess.

of their securities. The mere number of security holders gives little clue to the size of their individual holdings or to their actual ability to have a voice in the management. In fact, the concentration of stock ownership of corporations in the hands of a tiny minority of the population matches the concentration of corporate assets.

The year 1929 was a banner year for distribution of stock ownership.

But in that year three-tenths of 1 per cent of our population received 78 per cent of the dividends reported by individuals. This has roughly the same effect as if, out of every 300 persons in our population, 1 person received 78 cents out of every dollar of corporate dividends while the other 299 persons divided up the other 22 cents among them.

The effect of this concentration is reflected in the distribution of national income.

A recent study by the National Resources Committee shows that in 1935-36—

"Forty-seven per cent of all American families and single individuals living alone had incomes of less than $1,000 for the year; and at the other end of the ladder a little less than 1½ per cent of the Nation's families received incomes which in dollars and cents reached the same total as the incomes of the 47 per cent at the bottom."

Furthermore, to drive the point home, the Bureau of Internal Revenue reports that estate tax returns in 1936 show that—

"Thirty-three per cent of the property which was passed by inheritance was found in only 4 per cent of all the reporting estates. (And the figures of concentration would be far more impressive, if we included all the smaller estates which, under the law, do not have to report.)"

We believe in a way of living in which political democracy and free private enterprises for profit should serve and protect each other—to insure a maximum of human liberty not for a few but for all.

It has been well said that, "The freest government, if it could exist, would not be long acceptable if the tendency of the laws were to create a rapid accumulation of property in few hands, and to render the great mass of the population dependent and penniless."

Today many Americans ask the uneasy question: Is the vociferation that our liberties are in danger justified by the facts?

Today's answer on the part of average men and women in every part of the country is far more accurate than it would have been in 1929 for the very simple reason that during the past 9 years we have been doing a lot of common-sense thinking. Their answer is that if there is that danger it comes from that concentrated private economic power which is struggling so hard to master our democratic government. It will not come, as some (by no means all) of the possessors of that private power would make the people believe—from our democratic government itself.

II. Financial Control over Industry

Even these statistics I have cited do not measure the actual degree of concentration of control over American industry.

Close financial control, through interlocking spheres of influence over channels of investment, and through the use of financial devices like holding companies and strategic minority interests, creates close control of the business policies of enterprises which masquerade as independent units.

That heavy hand of integrated financial and management control lies upon large and strategic areas of American industry. The small-business man is unfortunately being driven into a less and less independent position in American life. You and I must admit that.

Private enterprise is ceasing to be free enterprise and is becoming a cluster of private collectivisms; making itself as a system of free enterprise after the American model, it is in fact becoming a concealed cartel system after the European model.

We all want efficient industrial growth and the advantages of mass production. No one suggests that we return to the hand loom or hand forge. A series of processes involved in turning out a given manufactured product may well require one or more huge mass-production plants. Modern efficiency may call for this. But modern efficient mass production is not furthered by a central control which destroys competition between industrial plants each capable of efficient mass production while operating as separate units. Industrial efficiency does not have to mean industrial empire building.

And industrial empire building, unfortunately, has evolved into banker control of industry. We oppose that.

Such control does not offer safety for the investing public. Investment judgment requires the disinterested appraisal of other people's management. It becomes blurred and distorted if it is combined with the conflicting duty of controlling the management it is supposed to judge.

Interlocking financial controls have taken from American business much of its traditional virility, independence, adaptability, and daring—without compensating advantages. They have not given the stability they promised.

Business enterprise needs new vitality and the flexibility that comes from the diversified efforts, independent judgments and vibrant energies of thousands upon thousands of independent businessmen.

The individual must be encouraged to exercise his own judgment and to venture his own small savings, not in stock gambling but in new enterprise investment. Men will dare to compete against men but not against giants.

III. The Decline of Competition and Its Effects on Employment

In output per man or machine we are the most efficient industrial nation on earth.

In the matter of complete mutual employment of capital and labor we are among the least efficient.

Our difficulties of employing labor and capital are not new. We have had them since good, free land gave out in the West at the turn of the century. They were old before we undertook changes in our tax policy or in our labor and social legislation. They were caused not by this legislation but by the same forces which caused the legislation. The problem of bringing idle men and idle money together will not be solved by abandoning the forward steps we have

taken to adjust the burdens of taxation more fairly and to attain social justice and security.

If you believe with me in private initiative, you must acknowledge the right of well-managed small business to expect to make reasonable profits. You must admit that the destruction of this opportunity follows concentration of control of any given industry into a small number of dominating corporations.

One of the primary causes of our present difficulties lies in the disappearance of price competition in many industrial fields, particularly in basic manufacture where concentrated economic power is most evident and where rigid prices and fluctuating pay rolls are general.

Managed industrial prices mean fewer jobs. It is no accident that in industries like cement and steel where prices have remained firm in the face of a falling demand pay rolls have shrunk as much as 40 and 50 per cent in recent months. Nor is it mere chance that in most competitive industries where prices adjust themselves quickly to falling demand, pay rolls and employment have been far better maintained. By prices we mean, of course, the prices of the finished articles and not the wages paid to workers.

When prices are privately managed at levels above those which would be determined by free competition, everybody pays.

The contractor pays more for materials; the homebuilder pays more for his house; the tenant pays more rent; and the worker pays in lost work.

Even the Government itself is unable, in a large range of materials, to obtain competitive bids. It is repeatedly confronted with bids identical to the last cent.

Our housing shortage is a perfect example of how ability to control prices interferes with the ability of private enterprise to fill the needs of the community and provide employment for capital and labor.

On the other hand, we have some lines of business, large and small, which are genuinely competitive. Often these competitive industries must buy their basic products from monopolistic industry, thus losing, and causing the public to lose, a large part of the benefit of their own competitive policy. Furthermore, in times of recession, the practices of monopolistic industries make it difficult for business or agriculture, which is competitive and which does not curtail production below normal needs, to find a market for its goods even at reduced prices. For at such times a large number of customers of agriculture and competitive industry are being thrown out of work by those noncompetitive industries which choose to hold their prices rather than to move their goods and to employ their workers.

If private enterprise left to its own devices becomes half-regimented and half-competitive, half-slave and half-free, as it is today, it obviously cannot adjust itself to meet the needs and the demands of the country.

Most complaints for violations of the antitrust laws are made by businessmen against other businessmen. Even the most monopolistic businessman disapproves of all monopolies but his own. We may smile at this as being just an example of human nature, but we cannot laugh away the fact that the combined effect of the monopolistic controls which each business group imposes for its own benefit inevitably destroys the buying power of the Nation as a whole.

IV. Competition Does Not Mean Exploitation

Competition, of course, like all other good things, can be carried to excess. Competition should not extend to fields where it has demonstrably bad social and economic consequences. The exploitation of Child labor, the chiseling of workers' wages, the stretching of workers' hours, are not necessary, fair, or proper methods of competition. I have consistently urged a Federal wages-and-hours bill to take the minimum decencies of life for the working man and woman out of the field of competition.

It is, of course, necessary to operate the competitive system of free enterprise intelligently. In gaging the market for their wares businessmen, like the farmers, should be given all possible information by government and by their own associations so that they may act with knowledge and not on impulse. Serious problems of temporary overproduction can and should be avoided by disseminating information that will discourage the production of more goods than the current markets can possibly absorb or the accumulation of dangerously large inventories for which there is no obvious need.

It is, of course, necessary to encourage rises in the level of those competitive prices, such as agricultural prices, which must rise to put our price structure into more workable balance and make the debt burden more tolerable. Many such competitive prices are now too low.

It may at times be necessary to give special treatment to chronically sick industries which have deteriorated too far for natural revival, especially those which have a public or quasi-public character.

But generally over the field of industry and finance we must revive and strengthen competition if we wish to preserve and make workable our traditional system of free private enterprise.

The justification of private profit is private risk. We cannot safely make America safe for the businessman who does not want to take the burdens and risks of being a businessman.

V. The Choice Before Us

Examination of methods of conducting and controlling private enterprise which keep it from furnishing jobs or income or opportunity for one-third of the population is long overdue on the part of those who sincerely want to preserve the system of private enterprise for profit.

No people, least of all a democratic people, will be content to go without work or to accept some standard of living which obviously and woefully falls short of their capacity to produce. No people, least of all a people with our traditions of personal liberty, will endure the slow erosion of opportunity for the common man, the oppressive sense of helplessness under the domination of a few, which are overshadowing our whole economic life.

A discerning magazine of business has editorially pointed out that big-business collectivism in industry compels an ultimate collectivism in government.

The power of a few to manage the economic life of the Nation must be diffused among the many or be transferred to the public and its democratically

responsible government. If prices are to be managed and administered, if the Nation's business is to be allotted by plan and not by competition, that power should not be vested in any private group or cartel, however benevolent its professions profess to be.

Those people, in and out of the halls of government, who encourage the growing restriction of competition either by active efforts or by passive resistance to sincere attempts to change the trend, are shouldering a terrific responsibility. Consciously or unconsciously they are working for centralized business and financial control. Consciously or unconsciously they are therefore either working for control of the Government itself by business and finance or the other alternative—a growing concentration of public power in the Government to cope with such concentration of private power.

The enforcement of free competition is the least regulation business can expect.

VI. A Program

The traditional approach to the problems I have discussed has been through the antitrust laws. That approach we do not propose to abandon. On the contrary, although we must recognize the inadequacies of the existing laws, we seek to enforce them so that the public shall not be deprived of such protection as they afford. To enforce them properly requires thorough investigation not only to discover such violations as may exist but to avoid hit-and-miss prosecutions harmful to business and government alike. To provide for the proper and fair enforcement of the existing antitrust laws I shall submit, through the Budget, recommendations for a deficiency appropriation of $200,000 for the Department of Justice.

But the existing antitrust laws are inadequate—most importantly because of new financial economic conditions with which they are powerless to cope.

The Sherman Act was passed nearly 40 years ago. The Clayton and Federal Trade Commission Acts were passed over 20 years ago. We have had considerable experience under those acts. In the meantime we have had a chance to observe the practical operation of large-scale industry and to learn many things about the competitive system which we did not know in those days.

We have witnessed the merging out of effective competition in many fields of enterprise. We have learned that the so-called competitive system works differently in an industry where there are many independent units, from the way it works in an industry where a few large producers dominate the market.

We have also learned that a realistic system of business regulation has to reach more than consciously immoral acts. The community is interested in economic results. It must be protected from economic as well as moral wrongs. We must find practical controls over blind economic forces as well as over blindly selfish men.

Government can deal and should deal with blindly selfish men. But that is a comparatively small part—the easier part—of our problem. The larger, more important, and more difficult part of our problem is to deal with men who are not selfish and who are good citizens, but who cannot see the social and economic consequences of their actions in a modern economically interdependent

community. They fail to grasp the significance of some of our most vital social and economic problems because they see them only in the light of their own personal experience and not in perspective with the experience of other men and other industries. They therefore fail to see these problems for the Nation as a whole.

To meet the situation I have described, there should be a thorough study of the concentration of economic power in American industry and the effect of that concentration upon the decline of competition. There should be an examination of the existing price system and the price policies of industry to determine their effect upon the general level of trade, upon employment, upon long-term profits, and upon consumption. The study should not be confined to the traditional antitrust field. The effects of tax, patent, and other Government policies cannot be ignored.

The study should be comprehensive and adequately financed. I recommend an appropriation of not less than $500,000 for the conduct of such comprehensive study by the Federal Trade Commission, the Department of Justice, the Securities and Exchange Commission, and such other agencies of government as have special experience in various phases of the inquiry.

I enumerate some of the items that should be embraced in the proposed study. The items are not intended to be all inclusive. One or two of the items, such as bank holding companies and investment trusts, have already been the subject of special study, and legislation concerning these need not be delayed.

(1) *Improvement of antitrust procedure.*—A revision of the existing antitrust laws should make them susceptible of practical enforcement by casting upon those charged with violations the burden of proving facts peculiarly within their knowledge. Proof by the Government of identical bids, uniform price increases, price leadership, higher domestic than export prices, or other specified price rigidities might be accepted as prima facie evidence of unlawful actions.

The Department of Justice and the Federal Trade Commission should be given more adequate and effective power to investigate whenever there is reason to believe that conditions exist or practices prevail which violate the provisions or defeat the objectives of the antitrust laws. If investigation reveals border-line cases where legitimate coöperative efforts to eliminate socially and economically harmful methods of competition in particular industries are thwarted by fear of possible technical violations of the antitrust laws, remedial legislation should be considered.

As a really effective deterrent to personal wrongdoing, I would suggest that where a corporation is enjoined from violating the law, the court might be empowered to enjoin the corporation for a specified period of time from giving any remunerative employment or any official position to any person who has been found to bear a responsibility for the wrongful corporate action.

As a further deterrent to corporate wrongdoing the Government might well be authorized to withhold Government purchases from companies guilty of unfair or monopolistic practice.

(2) *Mergers and interlocking relationships.*—More rigid scrutiny through the Federal Trade Commission and the Securities and Exchange Commission

of corporate mergers, consolidations, and acquisitions than that now provided by the Clayton Act to prevent their consummation when not clearly in the public interest; more effective methods for breaking up interlocking relationships and like devices for bestowing business by favor.

(3) *Financial controls.*—The operations of financial institutions should be directed to serve the interests of independent business and restricted against abuses which promote concentrations of power over American industry.

(*a*) *Investment trusts.*—Investment trusts should be brought under strict control to insure their operations in the interests of their investors rather than of their managers. The Securities and Exchange Commission is to make a report to Congress on the results of a comprehensive study of investment trusts and their operations which it has carried on for nearly 2 years. The investment trust, like the holding company, puts huge aggregations of the capital of the public at the direction of a few managers. Unless properly restricted, it has potentialities of abuse second only to the holding company as a device for the further centralization of control over American industry and American finance.

The tremendous investment funds controlled by our great insurance companies have a certain kinship to investment trusts, in that these companies invest as trustees the savings of millions of our people. The Securities and Exchange Commission should be authorized to make an investigation of the facts relating to these investments with particular relation to their use as an instrument of economic power.

(*b*) *Bank holding companies.*—It is hardly necessary to point out the great economic power that might be wielded by a group which may succeed in acquiring domination over banking resources in any considerable area of the country. That power becomes particularly dangerous when it is exercised from a distance and notably so when effective control is maintained without the responsibilities of complete ownership.

We have seen the multiplied evils which have arisen from the holding-company system in the case of public utilities, where a small minority ownership has been able to dominate a far-flung system.

We do not want those evils repeated in the banking field, and we should take steps now to see that they are not.

It is not a sufficient assurance against the future to say that no great evil has yet resulted from holding-company operations in this field. The possibilities of great harm are inherent in the situation.

I recommend that the Congress enact at this session legislation that will effectively control the operation of bank-holding companies; prevent holding companies from acquiring control of any more banks, directly or indirectly; prevent banks controlled by holding companies from establishing any more branches; and make it illegal for a holding company, or any corporation or enterprise in which it is financially interested, to borrow from or sell securities to a bank in which it holds stock.

I recommend that this bank legislation make provision for the gradual separation of banks from holding-company control or ownership, allowing a reasonable time for this accomplishment—time enough for it to be done in

an orderly manner and without causing inconvenience to communities served by holding-company banks.

(4) *Trade associations.*—Supervision and effective publicity of the activities of trade associations, and a clarification and delineation of their legitimate spheres of activity which will enable them to combat unfair methods of competition, but which will guard against their interference with legitimate competitive practices.

(5) *Patent laws.*—Amendment of the patent laws to prevent their use to suppress inventions, and to create industrial monopolies. Of course, such amendment should not deprive the inventor of his royalty rights, but, generally speaking, future patents might be made available for use by anyone upon payment of appropriate royalties. Open patent pools have voluntarily been put into effect in a number of important industries with wholesome results.

(6) *Tax correctives.*—Tax policies should be devised to give affirmative encouragement to competitive enterprise.

Attention might be directed to increasing the intercorporate dividend tax to discourage holding companies and to further graduating the corporation income tax according to size. The graduated tax need not be so high as to make bigness impracticable, but might be high enough to make bigness demonstrate its alleged superior efficiency.

We have heard much about the undistributed profits tax. When it was enacted 2 years ago, its objective was known to be closely related to the problem of concentrated economic power and a free capital market.

Its purpose was not only to prevent individuals whose incomes were taxable in the higher surtax brackets from escaping personal income taxes by letting their profits be accumulated as corporate surplus. Its purpose was also to encourage the distribution of corporate profits so that the individual recipients could freely determine where they would reinvest in a free capital market.

It is true that the form of the 1936 tax worked a hardship on many of the smaller corporations. Many months ago I recommended that these inequities be removed.

But in the process of the removal of inequities, we must not lose sight of original objectives. Obviously the Nation must have some deterrent against special privileges enjoyed by an exceedingly small group of individuals under the form of the laws prior to 1936, whether such deterrent take the form of an undistributed-profits tax or some other equally or more efficient method. And obviously an undistributed profits tax has a real value in working against a further concentration of economic power and in favor of a freer capital market.

(7) *Bureau of Industrial Economics.*—Creation of a Bureau of Industrial Economics which should be endowed with adequate powers to supplement and supervise the collection of industrial statistics by trade associations. Such a bureau should perform for businessmen functions similar to those performed for the farmers by the Bureau of Agricultural Economics.

It should disseminate current statistical and other information regarding market conditions and be in a position to warn against the dangers of temporary overproduction and excessive inventories as well as against the dangers of shortages and bottleneck conditions and to encourage the maintenance of

orderly markets. It should study trade fluctuations, credit facilities, and other conditions which affect the welfare of the average businessman. It should be able to help small-business men to keep themselves as well informed about trade conditions as their big competitors.

No man of good faith will misinterpret these proposals. They derive from the oldest American traditions. Concentration of economic power in the few and the resulting unemployment of labor and capital are inescapable problems for a modern "private enterprise" democracy. I do not believe that we are so lacking in stability that we will lose faith in our own way of living just because we seek to find out how to make that way of living work more effectively.

This program should appeal to the honest common sense of every independent businessman interested primarily in running his own business at a profit rather than in controlling the business of other men.

It is not intended as the beginning of any ill-considered "trust-busting" activity which lacks proper consideration for economic results.

It is a program to preserve private enterprise for profit by keeping it free enough to be able to utilize all our resources of capital and labor at a profit.

It is a program whose basic purpose is to stop the progress of collectivism in business and turn business back to the democratic competitive order.

It is a program whose basic thesis is not that the system of free private enterprise for profit has failed in this generation, but that it has not yet been tried.

Once it is realized that business monopoly in America paralyzes the system of free enterprise on which it is grafted, and is as fatal to those who manipulate it as to the people who suffer beneath its impositions, action by the Government to eliminate these artificial restraints will be welcomed by industry throughout the Nation.

For idle factories and idle workers profit no man.

FRANKLIN D. ROOSEVELT

THE WHITE HOUSE, *April 29, 1938*

APPENDIX B

JOINT RESOLUTION To create a temporary national economic committee[1]

Resolved by the Senate and House of Representatives of the United States of America in Congress assembled, That there is hereby established a temporary national economic committee (hereinafter referred to as the "committee"), to be composed of (1) three Members of the Senate, to be appointed by the President of the Senate; (2) three Members of the House of Representatives, to be appointed by the Speaker of the House of Representatives; and (3) one representative from each of the following departments and agencies, to be designated by the respective heads thereof: Department of Justice, Department of the Treasury, Department of Labor, Department of Commerce, the Securities and Exchange Commission, and the Federal Trade Commission. Such representative may designate an alternate to sit and act for him on the committee in his absence. Any such alternate, while so acting, shall have the same rights, powers, and duties as are conferred and imposed upon a member of the committee by this joint resolution. Any member appointed under clauses (1) and (2) may, when unable to attend a meeting of the committee, authorize another such member to act and vote for him in his absence. A vacancy in the committee shall not affect the power of the remaining members to executive [*sic*] the functions of the committee and shall be filled in the same manner as the original selection.

SEC. 2.

It shall be the duty of the committee—

(a) To make a full and complete study and investigation with respect to the matters referred to in the President's message of April 29, 1938, on monopoly and the concentration of economic power in and financial control over production and distribution of goods and services and to hear and receive evidence thereon, with a view to determining, but without limitation, (1) the causes of such concentration and control and their effect upon competition; (2) the effect of the existing price system and the price policies of industry upon the general level of trade, upon employment, upon long-term profits, and upon consumption; and (3) the effect of existing tax, patent, and other Government policies upon competition, price levels, unemployment, profits, and consumption; and shall investigate the subject of governmental adjustment of the purchasing power of the dollar so as to attain 1926 commodity price levels; and

(b) To make recommendation to Congress with respect to legislation upon the foregoing subjects, including the improvement of antitrust policy and procedure and the establishment of national standards for corporations engaged in commerce among the States and with foreign nations.

[1] Pub. Res. No. 113, 75th Cong., chap. 456, 3rd sess.; S. J. Res. 300.

SEC. 3.

(a) The committee shall have power to appoint subcommittees to assist the committee in its work. The members of the committee shall serve without additional compensation but shall be reimbursed for travel, subsistence, and other necessary expenses incurred by them in the exercise of the functions vested in the committee.

(b) The Department of Justice, Department of the Treasury, Department of Labor, Department of Commerce, the Securities and Exchange Commission, and the Federal Trade Commission are directed to appear before the committee or its designee and present evidence by examination of witnesses or the introduction of documents and reports. The evidence presented by each of these agencies shall cover the subject matter of this inquiry which is within its administrative jurisdiction under existing law or which may be assigned to such agencies by the committee. Each such agency is authorized to request the committee to issue such subpoenas as such agency may require for the attendance of witnesses and the production of documents and reports.

(c) The committee shall have power to employ and fix the compensation of such officers, experts, and employees as it deems necessary for the performance of its duties. The committee is authorized to utilize the services, information, facilities, and personnel of the departments and agencies of the Government.

SEC. 4.

(a) Prior to the opening of the first session of the Seventy-sixth Congress or as soon thereafter as is practicable the committee shall transmit to the President and to the Congress preliminary reports of the studies and investigations carried on by it, and by the departments and agencies represented thereon, together with the findings and recommendations of the committee, and shall submit to the President and to the Congress as soon as practicable thereafter, during or prior to the termination of the Seventy-sixth Congress, further and final reports of the studies and investigations carried out pursuant to this resolution, together with the findings and recommendations of the committee.

(b) A majority of the committee shall constitute a quorum, and the powers conferred upon them by this joint resolution may be exercised by a majority vote.

(c) All authority conferred by this joint resolution shall terminate upon the expiration of the Seventy-sixth Congress.

SEC. 5.

For the purpose of this joint resolution the committee, or any subcommittee designated by it, shall be entitled to exercise the same powers and rights as are conferred upon the Securities and Exchange Commission by subsection (c) of section 18 of the Act of August 26, 1935 (49 Stat. 831); and the provisions of subsections (d) and (e) of such section shall

be applicable to all persons summoned by subpoena or otherwise to attend and testify or to produce books, papers, correspondence, memoranda, contracts, agreements, or other records and documents before the committee.

SEC. 6.

(a) There is hereby authorized to be appropriated, out of any money in the Treasury not otherwise appropriated, the sum of $500,000, or so much thereof as may be necessary, to carry out the provisions of this joint resolution.

(b) Of the funds authorized to be appropriated under subsection (a), not to exceed $100,000 shall be immediately available for expenditure by the committee in carrying out its functions and not to exceed $400,000 shall be available, as the President shall direct, among the departments and agencies represented on the committee to enable them to carry out their functions under this joint resolution.

Final Reports

Final report and recommendations of the Temporary National Economic Committee. Recommendations of the Committee to the President and the Congress of the United States. Verbatim record of the public sessions of Committee members, containing the statement of the chairman, Senator Joseph C. O'Mahoney, progress report of the executive secretary, Dewey Anderson, statement of Thurman Arnold, Corwin Edwards, W. T. Kelley, James A. Horton, Wayne C. Taylor, Paul C. Truitt, Frank Bane, A. H. Martin, Frederick V. Waugh, Conway P. Coe, Louis H. Bean, Carl C. Taylor, Mordecai Ezekiel, Donald E. Montgomery, Sumner T. Pike, Senator James M. Mead, Isador Lubin, Willis J. Ballinger, Joseph J. O'Connell, final statement of the chairman. A Brief History of the Temporary National Economic Committee. A Financial Statement of the Committee's Operations. Pp. 783. $1.00.

Final report of the executive secretary to the Temporary National Economic Committee on the concentration of economic power in the United States. A staff volume prepared under the direction of Dr. Dewey Anderson, Executive Secretary of the Committee, and Dr. Theodore J. Kreps, Economic Adviser to the Committee, assisted by Ruth Aull. Competition and monopoly in American industry; concentration of production; managed industrial prices; controlled production and sales; trade associations and cartels; technology in our economy; interstate trade barriers; concentration of corporate assets, earnings, and profits; concentration of ownership; concentration of savings; concentrated control of investment policies; investments and the insurance industry; stimulating investment; investment in the housing industry; small business; consumers; fiscal policy and taxation. Pp. 435. 55c.

Final statement of Senator J. C. O'Mahoney, chairman of the Temporary National Economic Committee. Made at the closing public session to consider recommendations, March 11, 1941; presented by Mr. Barkley, April 1, 1941, Pp. 17. 5c.

VOLUME XXXII SEPTEMBER, 1942 NUMBER THREE

THE BURDEN OF A DOMESTIC DEBT

By B. U. RATCHFORD

I

Since the beginning of modern public debts there have been serious differences of opinion as to whether they are a blessing, a curse, or a matter of indifference. During the past ten years the discussions of deficit financing have revived this issue but apparently have done little to settle it. Those who, following the Keynesian analysis, have favored deficit financing have concentrated their attention upon the income-generating potentialities of debt creation and have dismissed the question of the burden of the debt in later years with the general statement that an internally-held debt imposes no economic burden. On the other hand, those who have made special studies of the latter question have frequently arrived at a different conclusion.[1]

Since the federal debt will increase greatly during the present war, it is a matter of considerable importance to know whether that debt will be an economic burden in the post-war years. It might influence our attitude toward borrowing during the war; it would certainly affect our attitude toward deficit financing after the war.

In the discussion which follows it is assumed that the large post-war debt will be held internally, that a considerable proportion will be held by commercial banks, and that the debt will never be reduced substantially, but that interest will be paid regularly. It is also assumed that Congress will continue to frame tax laws as in the past, giving more heed to political than to economic considerations, but that the level of taxation will be much higher than in the past, with considerable reliance upon a progressive personal income tax and a heavy corporate income tax.

It should be emphasized that the point under consideration is the

[1] See, for example: Ursula K. Hicks, *The Finance of British Government, 1920-1936* (London, 1938), pp. 341, 348; Dan Throop Smith, "Economic Consequences of Deficit Financing: A Review," *Am. Econ. Rev.*, Suppl., Vol. XXXI (Feb. 1941), p. 95; David McC. Wright, *The Creation of Purchasing Power* (Cambridge, 1942), pp. 148-49.

burden, if any, of an internally-held public debt after it has been incurred, irrespective of the effects caused by its incurrence. Too frequently these two considerations have been confused, but as Hansen aptly states, "Once the debt has been incurred, its subsequent impact upon employment and the distribution of income will be the same regardless of the purpose for which it was incurred."[2]

II

There are two methods of analysis which may be used in attacking this problem; the "real" or barter analysis and the monetary analysis. These two methods may, in certain circumstances, lead to quite different conclusions. Much of the prevailing confusion undoubtedly arises from the unconscious switching from one method of analysis to the other.

The real or barter analysis is characteristic of classical and neoclassical theory; it has been, as Wright states, "almost the hall-mark of a trained economist."[3] Under this analysis goods exchange for goods, effective competition prevails, prices are flexible, and unemployment cannot be a serious problem. This procedure does not recognize money or monetary institutions as important elements in any problem; only the factors of production can enter into the analysis. This position is succinctly summarized in John Stuart Mill's famous statement,

> There cannot, in short, be intrinsically a more insignificant thing in the economy of society, than money; except in the character of a contrivance for sparing time and labour. It is a machine for doing quickly and commodiously, what would be done, though less quickly and commodiously, without it; and like many other kinds of machinery, it only exerts a distinct and independent influence of its own when it gets out of order.[4]

In practice the last qualification was almost invariably forgotten or disregarded.

In other words, classical theory assumed that monetary institutions merely provided a colorless or neutral medium through which the real factors of production operated. If that medium became defective and thus interfered with the free functioning of the factors of production, that did not call for any modification of theory, but merely for a removal of the defect.

According to the monetary analysis, economic activity is dominated by the possibility of money profits. No matter how abundant the factors

[2] Alvin H. Hansen, *Fiscal Policy and Business Cycles* (New York, 1941), pp. 152-53. See also B. F. Haley, "The Federal Budget: Economic Consequences of Deficit Financing," *Am. Econ. Rev.*, Suppl., Vol. XXXI (Feb., 1941), p. 7.

[3] Wright, op. cit., p. 4. See this reference for a further, and excellent, discussion of this point.

[4] *Principles of Political Economy* (Ashley ed., London, 1921), p. 488.

of production may be, they will not be used nor will exchange take place unless there is the prospect of monetary gain. Say's Law no longer reigns supreme. Expectations, the propensity to consume, and especially liquidity preference must all enter the analysis, though none of them is a factor of production. In short, this analysis recognizes that monetary institutions and arrangements may cause a shortage or a surplus of purchasing power which, in turn, may affect incomes and the level of economic activity.

Under conditions of relatively full employment these two methods of analysis may yield approximately the same results, but under other conditions the results may vary widely.

Deficit financing is usually justified by use of the monetary analysis, which indicates that in certain circumstances monetary conditions may constitute an obstacle to the free and full use of economic resources. The remedy indicated by such analysis is to remove the obstacle by certain financial measures—the creation of purchasing power by borrowing. When this diagnosis and its corresponding prescription have been accepted and acted upon, however, its exponents are likely to switch, unconsciously, to the barter analysis to prove that the results of those financial measures (debts) cannot constitute an obstacle or burden in the future. Of course, in a barter economy they would be right. But it is submitted that greater consistency in method would provide a more valid and a more convincing analysis. It is the purpose here, with only minor exceptions, to stick to the monetary analysis.

III

A public debt will not constitute a net economic burden unless its disadvantages outweigh its advantages. Are there any advantages in the mere existence of a public debt? Hansen mentions several possible advantages. First, the English debt in the nineteenth century encouraged the growth of certain financial institutions such as banks, the stock market, and life insurance companies. Also, by offering capitalists maximum safety for a part of their funds, it encouraged them to take risks with the remainder and thus promoted the growth of new industries. Second, that same debt, together with a regressive tax system, curtailed consumption, increased savings, and thus facilitated the growth of capital and, ultimately, a rise in the standard of living. Third, because of a reversal of the above conditions, the English debt after World War I may have stimulated consumption.[5] Hansen only "suggests" this last point and does not attempt to prove it. It is not convincing to the present writer.[6]

[5] Hansen, *op. cit.*, pp. 154-57.

[6] See Hicks, *op. cit.*, pp. 356-57.

In addition to those mentioned by Hansen, other advantages have been suggested. Some have claimed that the existence of safe public securities stimulates thrift and savings by those of low incomes and leads to financial security and self-respect. Again, the public debt is a convenient legal investment for trust and other fiduciary funds. Finally, the public debt is the most feasible vehicle for central bank open-market operations.

Concerning all of these except Hansen's last point, which is of doubtful validity, it may be said either that they are no longer of economic significance or that the conditions may be met with only a moderate debt. The big problem of the future will not be the stimulation of savings but rather the finding of suitable uses for those savings. We have the machinery, the techniques, and the institutions for assembling savings and issuing high-grade private securities; our greatest lack, in times of peace, is adequate demand for investment funds. Also, there can be no doubt that the present volume of public bonds is sufficient to provide the convenience mentioned in the last two points. The conclusion which logically follows is that there would be no economic advantage in the existence of any additional public debt.

IV

Perhaps the most popular explanation for the widely-accepted doctrine that an internally-held public debt imposes no economic burden is the "one big family" analogy; one segment of our population owes another segment, and for the group as a whole the assets and liabilities cancel out. A few years ago Professor King used a similar analogy in attempting to explain the unemployment problem, dreaming up a situation which might have arisen on George Washington's plantation. He concluded that "the illustration does not depart widely from the situation as it exists today. The United States is little more than an enlargement of Washington's plantation."[7] In reply Professor Colm pointed out that "he neglects the difference which exists between an economic order based on private enterprise and an economy in which a leader tells his slaves what work they must do."[8] Those who use the family analogy do not specify whether the different members of the family maintain separate accounting systems and separate bank accounts. If they do, and if they deal with each other at arm's length, heavy debts owing from some members to others could play havoc with the family economy. If they do not, then the family is a communal unit and any

[7] Wilford I. King, "Are We Suffering from Economic Maturity?" *Jour. of Pol. Econ.*, Vol. XLVII (Oct., 1939), pp. 611-13.

[8] Gerhard Colm, "Comments on W. I. King: 'Are We Suffering from Economic Maturity?'" *Ibid.*, Vol. XLVIII (Feb., 1940), p. 115.

analogy between it and our national economy is invalid, as Colm has indicated.

Another and more technical explanation is that a public debt is no economic burden because debt charges are "transfer" rather than "exhaustive" payments; that is, they do not tie up man power or economic resources. With certain exceptions to be noted below, this is correct as a "real" analysis. But when the economic system is operating far below capacity, as it has chronically done in recent years, available man power and economic resources do not constitute the effective limit on production. Rather, the limit is the will or desire to use those factors. In other words, the possibility of profits is the critical factor and the monetary analysis is called for. Most of the analysis which follows is an attempt to determine whether the "transfer" payments necessary to service a debt may constitute an economic burden.

V

The strongest case for the proposition that a domestic debt is not an economic burden would be one in which the bonds are held by taxpayers in the same proportion as they pay taxes. It is usually argued that in such a case taxpayers are merely transferring money from one pocket to another and that the transfer can have no economic significance. Actually we have little data on the bond holdings of individuals and business units. Even if we had such data it is doubtful whether we could distribute the tax burden in the same pattern and even more doubtful whether we should do so. For example, millions of people are unable or unwilling, for various reasons, to buy bonds during this war. Can we, twenty years from now, so shape our tax system as to exempt them from that part of the tax burden represented by debt service? Should we do it if we could? Finally, even if we solve this problem at a given time it would not remain solved, for the ownership of bonds and the factors which determine tax liability are constantly changing.[9]

But even if the tax load could be distributed according to the ownership of bonds a public debt might, for several reasons, constitute a net economic burden. The first is the subjective reason. As Miss Ruggles has well stated:

> It is very doubtful whether or not individuals would realize that part of their taxes was being returned to them in the form of interest on their bonds. Even if they realized that this was true, it is doubtful whether or not they would find their taxes less burdensome for that reason, since most individuals, who give any consideration at all to the matter when they buy government bonds,

[9] See A. C. Pigou, *The Political Economy of War* (new and rev. ed.; New York, 1941), p. 77.

expect that the interest they will receive from their bonds will exceed the taxes they must pay for debt service.[10]

In brief, the bondholder takes his interest income for granted. He reasons, quite correctly, that he might have put his funds into other securities and therefore he should not be penalized for having bought government bonds. Even though the taxes he pays come back to him in interest he will try just as hard to escape them, he will regard them with as much distaste, and they will influence his economic decisions and actions just as much as though they went to pay interest to some one else.

More tangible—and more "real"—than the subjective factors are the various frictions involved in levying and collecting the taxes necessary to service a debt. Some writers seem to imply that when additional revenues are needed Congress merely changes a few figures in the tax laws, taxpayers make corresponding changes in their computations, and that ends the matter. They would have us believe that the taxpayer is the meekest of lambs whose only joy is to be shorn. Actually, the levy and collection of new taxes is a long, bitter, and costly fight from beginning to end. The mere mechanics of passing the laws, interpreting them, settling disputes, collecting the revenues, and paying out funds require the services of thousands of men.[11] Let us note some recent developments.

During the past ten years federal taxes have been increased sharply. A new revenue act has been passed every year—two were enacted in 1940—in contrast with the usual biennial act in the twenties. Several of the acts were marked by particularly bitter fights. From 1936 to 1938, the undistributed profits tax not only caused Congress much trouble but also was a very disturbing element in the business and financial worlds. In 1940, the start of our defense program was delayed for weeks while business men held out for tax concessions. The Revenue act of 1941 was under consideration from April to September while congressional committees held hearings and drafted compromises. Hundreds of men spent thousands of days and more thousands of dollars preparing briefs and pleading their cases. Even the President was constrained to intervene before the fight was over. Certainly the costs of such legislation must be measured in the millions of dollars.

[10] Catherine G. Ruggles, "Social and Economic Implications of the National Debt," *Annals Am. Acad. Pol. and Soc. Sci.*, Vol. 214 (Mar., 1941), pp. 200-01. *Cf.*, "no one would buy bonds if his entire income from them were going to be taxed away." Wright, *op. cit.*, p. 143. *Cf.* also: Haley, *op. cit.*, p. 79; and Dan T. Smith, *op. cit.*, pp. 95-96.

[11] "Moreover, the necessity of passing an increasing proportion of the national income through the public treasury is attended by growing difficulties and costs of levy, collection, and transfer." Lawrence H. Seltzer, "Direct Versus Fiscal and Institutional Factors," *Am. Econ. Rev.*, Suppl., Vol. XXXI (Feb., 1941), p. 105.

Tax litigation has increased greatly in recent years. The Supreme Court of the United States decides from fifty to sixty tax cases per session—more than in any other field. All large business units must have their expensive tax specialists and subscribe to elaborate tax services.[12] More accountants and lawyers are specializing in tax work.

These developments are not surprising and are perhaps unavoidable. Additional revenues mean new taxes and higher rates on old taxes, which require larger tax payments by business units and individuals with large incomes. The larger payments make it worth while for those affected to contest the constitutionality of new taxes and to try to find loopholes in old laws, all of which means more litigation. Also, in the search for new sources of revenue, Congress must resort to new and untried taxes, the constitutionality of which may be questionable. Nor can we hope for relief after we have permanently attained a higher level of taxation. The economic situation is constantly changing, requiring changes in taxes. But even if it were stable, pressure groups would be constantly at work to shift tax burdens.[13] So long as rates are high, the premium for escaping taxes will be great, and the ingenuity of man will always be at work.[14]

The total costs of these mechanical frictions, aside from their disturbing influence upon the conduct of business, amounts to many millions of dollars per year. They represent a dead loss, a drag on economic production, even if the tax load is distributed in proportion to debt holdings. The uncertainties and disturbances which they arouse each year probably constitute a greater burden. So, even under the most favorable assumption of conditions which in practice are unattainable, a public debt is a burden.

VI

The most important factor determining the burden of a public debt is the effect the debt will have upon the creation of income in the future.

[12] "In recent years several factors have combined to increase greatly the business man's cost of compliance with tax laws; perhaps the most important of these factors are, first, the rapid development of various new and complicated forms of federal and state taxation applying to business. . . ." Robert Murray Haig, "The Cost to Business Concerns of Compliance with Tax Laws." *Manag. Rev.*, Vol. XXIV (1935), p. 324. He found that with the federal income tax the typical corporation had a compliance cost equal to 4.7 per cent of the tax. *Ibid.*, p. 327. New York City stores found that the cost of complying with the sales tax was equal to from five to ten per cent of the tax. Carl Shoup, "The Experience of Retailers under New York City's Sales Tax," *Bull. Nat. Tax Assoc.*, Vol. XXX (1936), p. 110.

[13] See "Economic Power and Political Pressures," T.N.E.C. monog. no. 26, pp. 34-35, 117-21.

[14] *Cf.* Hicks, *op. cit.*, p. 261: "Chancellors have been fighting a losing battle against the ingenuity of taxpayers who believe themselves to be hardly treated—and the ingenuity of their legal advisers."

In the past the existence of a public debt may have facilitated capital formation and the increase of real income. Taxes were regressive and the debt was held by the wealthy. This promoted savings, which were the limiting factor in the expansion of capital. Today conditions are different; investment, not savings, is the factor which limits the expansion of capital and income. It is therefore pertinent to consider how investment will be affected by the heavier taxes which will be necessary to service a large debt.[15]

It should require no extended analysis to demonstrate that heavy taxes are a deterrent to investment. We now rely, and presumably will continue to rely, heavily upon income and profits taxes. If business men are rational they will, when estimating the profitability of new investment, deduct from a third to a half of the anticipated net profits as taxes. That can mean only one thing: a drastic reduction in the range of profitable new enterprises. According to Hansen:

Even an ideal tax structure will restrain more or less the inducement to invest, and a regressive tax structure will unduly restrict consumption. Diversion of a large part of the income stream into interest payments on government bonds would tend to raise the propensity to save, thus intensifying the savings-investment problem.[16]

Angell goes into the problem more fully and lists heavy taxation as the most important factor which has reduced the demand for investment funds in recent years. He contends that both progressive income taxes and capital-gains taxes "hit especially hard those investors in the higher brackets who would otherwise take the risks of getting new enterprises started. . . ."[17] He concludes that

There is hence no major line of escape from the conclusion . . . that in all important cases, actual or even expected increases in those taxes of which the burden varies even roughly with individual or business income from assets must necessarily reduce the volume of subsequent new private investment below what it would otherwise have been.[18]

[15] There would, of course, be taxes even if there were no debt. In this respect, then, the taxes for debt service may be considered as marginal taxes. If we come out of the war with a debt requiring interest payments of 5 or 6 billion dollars—an amount equal to the total of federal revenues for any year before 1940—the taxes to raise that sum may mean the difference between total taxes of 30 per cent and 35 per cent of the national income; or between 35 per cent and 40 per cent.

[16] Hansen, *op. cit.*, p. 175. *Cf.*: "But with every increase in tax rates there is the danger that the marginal efficiency of capital and the propensity to consume will be adversely affected, and that consequently the increase in the national income may be checked." Haley, *op. cit.*, p. 84. See also, Hicks, *op. cit.*, pp. 249-50.

[17] James W. Angell, *Investment and Business Cycles* (New York, 1941), p. 273 footnote. See also: Dan T. Smith, *Am. Econ. Rev.*, Suppl., Vol. XXXI (Feb., 1941), pp. 95-96, and Imre de Vegh, "Savings, Investment, and Consumption," *ibid.*, pp. 244-45.

[18] Angell, *op. cit.*, p. 278.

Slichter is equally emphatic in his belief that taxes have been a major factor in restricting investment. He states that

> a deficit may cause the investment function to shift to the left, especially if it arouses the expectation of higher taxes and if the government has manifested a strong propensity to tax profits.

He then proceeds to show that the above possibility has been realized in this country.[19]

In addition to the quantitative effect upon expected profits, a large debt may deter investment in another way. Keynes and others who use his approach have emphasized the strategic part played by "expectations" or "anticipations" in determining the rate of new investment. Keynes pictures quite vividly the great uncertainty out of which these expectations arise and finally concludes that we usually rely upon a convention, *i.e.*, the assumption "that the existing state of affairs will continue indefinitely except in so far as we have specific reasons to expect a change."[20] Into this state of great uncertainty a large debt injects a powerful factor on the pessimistic side—the certainty of heavy taxes. Further, if the debt is increasing or if national income is decreasing the business man has a strong reason for believing that "the existing state of affairs" will not continue indefinitely but will get worse. In fact, there may be a "multiplier" at work to increase pessimism here. If revenues for debt service must be quadrupled, a given investor may fear that his share of the taxes may be increased to an even greater extent because of discriminatory taxes or because the tax structure may be made more progressive. So long as expectations retain their present importance and so long as we use progressive taxes a large debt will be a deterrent to private investment.

Thus we have the answer to the problem of why a domestic debt, although it merely takes money from one group and gives it to another, nevertheless constitutes a net burden. It is a burden because it discourages the creation of income. A progressive tax structure which bears heavily upon capital gains and income from property—and most large incomes are from property—takes funds away from strategic or income-generating points in the income stream and restores them to the stream at less strategic points.[21] The result is a reduction in the demand for investment funds and consequently in the expansion of

[19] Sumner H. Slichter, "The Conditions of Expansion," *Am. Econ. Rev.*, Vol. XXXII (Mar., 1942), pp. 5-7.

[20] J. M. Keynes, *The General Theory* (London, 1936), pp. 149-52.

[21] Kuznets refers to it as "a transfer of income from areas in which its power to stimulate production is great to others in which such power is less." Simon Kuznets, "National Income and Taxable Capacity," *Am. Econ. Rev.*, Suppl., Vol. XXXII (March, 1942), p. 59. See also Angell, *op. cit.*, p. 9 and de Vegh, *Am. Econ. Rev.*, Suppl., Vol. XXXI (Feb., 1941), p. 245.

capital and income. Further, this analysis provides an answer to the argument, frequently advanced, that a national debt cannot be a seriously disturbing factor so long as interest payments amount to only a small part of national income. The spark plugs represent only an infinitesimal part of an automobile's weight, but the car cannot function without them. Interest payments may represent only a small part of national income but they may be equal to a very large part of business profits; a part large enough, if taxed away from the owners of business, to stop all new investment.[22]

There is a wider and more general principle involved here. Our economic system is still basically one of private property and free enterprise; a system in which we depend upon the profit motive, especially as it works out through private investment, to provide the driving power for economic activity. We still assume that the income received by the various factors of production measures roughly the value of the contributions made by those factors to economic production. There is no other rational basis for our present system. But as larger and larger parts of our national income are run through the tax mechanism and distributed to holders of the public debt, the connection between contribution to economic production and the ultimate income enjoyed is weakened.[23] For example, if interest payments were equal to 25 per cent of the national income, producers would have to surrender 25 per cent of their economic rewards while bondholders would be able to claim that 25 per cent without making any contribution to production. Clearly that is not a good way to encourage economic production or to promote social harmony.[24]

It may be objected that the same argument would apply to interest on private debts. There are, however, two important differences. First,

[22] In a recent article Hansen faced this question and concluded, "Here is a question that has *got* to be solved" (italics supplied). Alvin H. Hansen and Guy Greer, "The Federal Debt and the Future," *Harper's* (April 1942), p. 498. He did not say nor indicate that it *can* be solved, yet he favors an indefinite increase in the federal debt. Here the words of J. M. Clark would seem to be appropriate; he said we should not commit "ourselves to a policy which would be disastrous if the measures should disappoint optimistic expectations. We must act daringly, but we can probably be daring without gambling our national safety on a single throw of dice. An experimental policy implies keeping open the possibility of withdrawal." *The Structure of the American Economy* (Washington, 1940), Vol. II, p. 26.

[23] There is no escape from this conclusion unless we assume that all necessary revenues could be collected from "surplus" incomes without in any way affecting economic activity. When the needed revenue is large this is obviously a false assumption.

[24] This is especially true of a war debt. It is very difficult for anyone to explain logically why ex-soldiers and those who were hard hit by inflation during a war should, in later years, help to pay interest to those who bought bonds during a war, perhaps out of exorbitant war profits.

the parties who pay interest on private debts have received a special benefit and in most cases their earning power has been increased by the loan. With public debts it is difficult, if not impossible, to establish such a connection. Second, the creditor of a private debtor must assume, in some degree, direction and control over his funds and decide where and how they shall be used; to this limited extent he must function as an entrepreneur. This is not true with public debts.

Perhaps Adam Smith had in mind some considerations like the above when he wrote

> a creditor of the public, considered merely as such, has no interest in the good condition of any particular portion of land, or in the good management of any particular portion of capital stock. As a creditor of the public he has no knowledge of any such particular portion. He has no inspection of it. He can have no care about it. Its ruin may in some cases be unknown to him, and cannot directly affect him.[25]

The above section raises the question whether there is any real difference between private and public investment. Many have argued that when the funds are used for productive purposes in both cases there is no essential difference.[26] Both private and public investment put to use funds which have been saved (or create new funds) and thus stimulate business activity for the time being. Also, both may create utilities. But there are two important differences. First, government enterprises do not have to pass "the test of the market." Government credit is such that the promoter of a project does not have to convince those who are to provide the funds that the project will be profitable.[27] Thus an important check against the wasteful use of economic resources is avoided. It is true that this check has often worked unsatisfactorily but it may still be better than no check. As Wright aptly notes, "To assume *prima facie* that government projects which are free are not worth their cost is doubtless erroneous, but it is equally erroneous to assume that they are."[28] Further, government investment is, by tradition, restricted to low-yield fields, for the fields which promise high yields have already been exploited by private investment. Also, management is likely, in general, to be more efficient in the private field because the private business man, in order to get

[25] *The Wealth of Nations* (Everyman's ed.), Vol. II, p. 410.

[26] See, for example, Richard V. Gilbert and others, *An Economic Program for American Democracy* (New York, 1938), pp. 63-67.

[27] On the contrary, he may have to prove that it would *not* be profitable or self-liquidating in the near future, lest it permits too rapid disinvestment or competition with private business. *Cf.:* Paul A. Samuelson, "The Theory of Pump-Priming Reëxamined," *Am. Econ. Rev.*, Vol. XXX (Sept., 1940), pp. 497-98.

[28] Wright, *op. cit.*, p. 145.

to the top, is subject to a more severe and rigid selection than is the politician.[29]

Second, the services rendered by public investments are paid for, not by those who use them and in proportion to that use, but by taxpayers. In other words, private activity must not only bear the costs of the utilities it creates but also pay for the utilities created by public investment.[30] We have seen that heavy taxation discourages investment and that investment funds have a strategic value. In the future the government may, in order to keep incomes up and to put savings to work, be forced to make additional investments, requiring still heavier taxes. In this way a vicious spiral may be set up, the government taking over a larger and larger portion of the economic sphere to find outlets for its investments and imposing heavier and heavier taxes upon the dwindling sphere of private economy.[31] Some contend that the increased income generated by public investment will make higher tax rates unnecessary. It has not proved so since 1933. In fact, the opposite may happen, for "The public debt may eventually become so large that a further increase in tax rates may decrease tax revenues by decreasing the national income."[32] Furthermore, the fear of higher taxes, whether justified or not, may deter private investment as much as the reality.[33]

VII

A large domestic debt may be burdensome for other reasons. The creation of a large debt means the creation of a large *rentier* class of individuals and institutions. These normally have considerable political influence which, in the post-war period, will be exerted in favor of deflation and drastic retrenchment. At the same time taxpayers will be demanding a "return to normalcy" and sweeping tax reduc-

[31] One writer asks: "Is it not conceivable that a market economy, if it relies solely on the possibility of expanding planned production whenever production for market contracts, may be obliged to transform itself into its opposite in order to stave off unemployment?" John H. G. Pierson, *Full Employment* (New Haven, 1941), p. 114. Kuznets asks, "If we are to retain the system of free enterprise and individual initiative . . . how far is it possible to yield to the pressure of secular factors making for expansion of governmental activity and at the same time assure an adequate rise of the national product?" *Am. Econ. Rev.*, Suppl., Vol. XXXII (Mar., 1942), p. 61.

[32] Haley, *Am. Econ. Rev.*, Suppl., Vol. XXXI (Feb., 1941), p. 84. *Cf.*: "Business psychology being what it is at present, the accumulation of deficits seems to have reached a point at which it now deters as much private investment as Government can make, or more. This would be still more strongly true of further deficits on a basis of policy pointing to indefinite future increases, and not limited to a temporary emergency." Clark, *op. cit.*, p. 25.

[33] See Clark, *op. cit.*, p. 20.

tions. That demand will have to be met in considerable part, for a free people will not, in time of peace, submit to the same rigorous scale of taxation which they will willingly bear in time of war.[34] The outcome of these two forces may well be a drastic reduction in the government's social expenditures during the critical reconstruction period and perhaps a failure to provide sufficient funds for national defense.

Opposing the *rentier* class—perhaps stimulated and augmented by *rentier* policies—will be certain inflationary groups such as farmers, manufacturers, debtors, and others. They may, in fact, have the first inning in the immediate post-war period, as in France after 1918. Political control may pass from one of these classes to the other, producing confusion and uncertainty in the economic world, or it may degenerate into a deadlock with the government trying to give each class a larger share of a steadily dwindling national income. The latter is essentially what happened in France after 1933; as one writer has expressed it, "they were simultaneously pursuing the policy of deflation and inflation too!"[35] There can be no doubt that the huge French debt was a major cause of the political confusion and the industrial lethargy which hung like a pall over France for the five or six years before 1939. In England it was found during the same period that "the hazards of a large accumulation of deadweight debt are even greater than had commonly been supposed" and that "The deflationary effect of the debt could not be side-stepped, yet it turned out to have inflationary effects just where they were not wanted."[36] In both countries the large debts were major causes of the financial, industrial, and military unpreparedness which prevailed when war came in 1939.

In brief, the point is this: In "a system of individual initiative and private enterprise . . . there must be some limit to the share of current income payments that can be withdrawn in the form of taxes."[37] If interest on the public debt consumes a larger part of that maximum, smaller amounts are left for social expenditures and for national defense. The pinch is most likely to be felt in times of depression, when a reduction of social expenditures may cause political conflicts and

[34] As Miss Ruggles well states, "Identical taxes involve a greater subjective burden after an emergency than during an emergency. During an emergency everyone may make sacrifices readily. But one cannot arouse enthusiasm to a very high pitch for paying taxes on account of a debt incurred during a past emergency." *Annals Am. Acad. Pol. and Soc. Sci.*, Vol. 214, p. 200.

[36] Hicks, *op. cit.*, pp. 358-59.

[37] Kuznets, *Am. Econ. Rev.*, Suppl., Vol. XXXII (Mar., 1942), p. 54. In time of peace the limit is substantially lower than in time of war. See also Ruggles, *Annals Am. Acad. Pol. and Soc. Sci.*, Vol. 214, pp. 204-05.

social unrest. Periods of depression are also periods in which wars are generated, thus the neglect of national defense may be disastrous.

Along a related line, Hansen raises the question "whether a public debt imposes any such serious rigidity upon the economy as is the case with private debt."[38] He does not think so because he does not think that the government is so likely to become insolvent. But a debt may impose rigidities and seriously curtail freedom of action without causing insolvency. In one respect, at least, public debt is like private debt; it curtails the debtor's freedom of action by prescribing in advance how a part of his income shall be allocated. The greater the debt, the greater the curtailment. In an emergency or under changed conditions, the debtor is unable to use all of his income as prevailing conditions may dictate; he must allocate a part of it in a way determined by previous commitments. In the final analysis this is probably the most important economic disadvantage of the whole institution of debt and would seem to be more significant than the purely legal fact of bankruptcy.[39]

VIII

In one other important respect an internal debt may be a burden, at least under conditions such as those now prevailing in the United States. It may complicate and interfere with the proper control of the monetary and banking system. At the end of this war the United States will owe the largest debt ever known in history. The average rate of interest paid on the bonds will be very low. It is at least possible that the prevailing rate of interest may rise in the next ten years. If it does rise, the price of government bonds, in the absence of strong support, will drop in proportion. Since 1937 the Federal Reserve System has followed the policy of supporting the government bond market in periods of emergency. On December 8, 1941, the Board of Governors issued a statement which read in part,

> The System is prepared to use its powers to assure that an ample supply of funds is available at all times for financing the war effort and to exert its influence toward maintaining conditions in the United States Government security market that are satisfactory from the standpoint of the government's requirements.
>
> Continuing the policy which was announced following the outbreak of war

[38] Hansen, *op. cit.*, p. 159.

[39] Hansen contends that "An internal loan resembles ordinary borrowing [evidently he means private borrowing] only in a purely formal way, and it is obvious that *every* analogy to private borrowing must be *completely* false" (italics supplied). *Ibid.*, p. 142. The above analysis indicates one way in which they are alike. In public borrowing there is more leeway before the limit is felt but when it is reached the consequences are all the more serious.

in Europe, Federal Reserve Banks stand ready to advance funds on United States Government securities at par to all banks.[40]

The System is practically forced to support the market since the commercial banks of the country are holding such a large amount of government bonds—over 22 billion dollars' worth—that any substantial price decline would threaten the solvency of the whole banking system. When the Reserve Banks buy bonds to support the market, however, they are not only coining the bonds into current purchasing power but they are also creating bank reserves which may be used as the basis for credit expansion.

Many of the sales of war savings bonds now being made are accomplished under the pressure of patriotic appeal. When the war is over and patriotic fervor subsides, it is probable that many small holders will redeem their bonds in order to purchase durable consumer goods. Business units may sell bonds in order to rehabilitate and to expand their plants in order to produce those goods. Other bondholders will sell if more attractive yields are available elsewhere. The rush to purchase goods may well touch off a boom such as followed the First World War. If, in order to support the market, the Reserve Banks are forced to buy several billion dollars of bonds they will only be adding fuel to the flames. Even if the bank reserves thus created could be sterilized or immobilized, there would still be the billions of dollars of purchasing power which would be created.

The basic fact is that it is now necessary for some agency to manipulate the price of government bonds. The only agency with sufficient resources to do that job is the central bank. But that task is, under certain conditions, inconsistent with the bank's major duty of controlling credit. It is quite evident that a situation may arise wherein it would be impossible for the Reserve Banks, with their present powers, to accomplish both of these objectives. Nor is it easy to prescribe the powers that would have to be given to the banks to enable them to deal successfully with the two problems. The only answer may be the retention by the government of its control over prices and production and an extension of direct governmental control over banking policies. In any case, the public debt will be a factor to be reckoned with; a factor which will solve no problems but which will complicate and intensify many.[41]

IX

We may briefly summarize our analysis. An internally-held public debt is an economic burden even when taxes are paid to service the

[40] *Federal Reserve Bulletin*, January, 1942, p. 2.

[41] For a penetrating and comprehensive discussion of how the debt has complicated the problem of monetary control in England, see Hicks, *op. cit.*, Part III.

debt in the same ratio as the bonds are held. This is true because of the friction of levying and collecting the taxes and because of the difference in the subjective effects of paying taxes and receiving interest. Most important, however, is the fact that such a debt is a burden because, when joined with a progressive tax system, it substantially restricts investment and thus lowers national income. Other elements of burden are the facts that a debt limits a government's freedom of action, tends to restrict social expenditures, and may preclude effective control of the monetary and banking system.

The whole analysis to this point indicates that one of the major difficulties is the progressive tax system which we are using and which we assumed at the beginning. Here we should recognize that a steeply progressive tax system and a free flow of investment funds may be incompatible. As Slichter expresses it, "There may be a clash . . . between the interest of the community in full employment and its preference concerning the distribution of wealth."[42]

It has been suggested that almost the whole burden of a domestic debt may be eliminated by a "proper" tax policy. For example, Wright states that the burden is "primarily a matter of tax friction. Careful tax policy could reduce it almost to the vanishing point."[43] Similar suggestions have been made elsewhere. But in what direction should we make the change? Toward a more progressive system, or toward a regressive system? Or in some other direction? None of those making the suggestion has indicated, even in a general way, how any feasible tax plan might be developed, so we are by no means sure that it *can* be done. Present conditions would seem to indicate that it *cannot* be done within the framework of our present economic system and we must work on that assumption until there is reasonable proof to the contrary. Even if an acceptable and promising plan could be devised by the theorist, there would probably be less than an even chance that it could be enacted and administered so as to attain the desired result. Finally, it should be noted that, when the debt is large and the tax load heavy, Congress cannot exercise fine discrimination in choosing the taxes it will impose; it will levy any and all taxes that promise to bring in sufficient revenue. "When the wisest government has exhausted all the proper subjects of taxation, it must, in cases of urgent necessity, have recourse to improper ones."[44]

In brief, it is highly doubtful whether the debt burden can be dissolved by manipulating the tax structure. While the doubt remains it is dangerous to keep on piling up the debt and thus increasing the

[43] Wright, *op. cit.*, p. 148.

[44] Adam Smith, *op. cit.*, Vol. II, p. 411.

burden for, as Clark says, we should keep open the possibility of withdrawal.

Public debt is, as Hansen suggests, an instrument of public policy, but it is one which should be used with care. It is not magic; it entails a cost which has to be paid in the future. How great that cost may be will depend partly on how well we manage our finances and partly on future conditions. When we choose to remove a monetary obstacle to present production or to finance a war by creating a debt, we are able to do so because we have freedom of action. But by that act we give hostages to the future; we restrict our freedom of action to deal with new problems which may arise and at the same time create an obstacle which, according to the best of our knowledge at present, will be a chronic economic problem.

CAPITAL MONEY AND REVENUE FUNDS

By Donald S. Tucker

Uninvested savings, we shall find, have at each moment a balance-sheet magnitude as precise as that of a bank deposit. This magnitude changes from hour to hour and from year to year. Alterations of this magnitude have highly significant consequences. One of the most dangerous economic fallacies is, then, the idea that saving equals investment. Real saving is but another aspect of real investment; but it is financial saving, not real saving, that diminishes the demand for goods and expands the demand for securities.

Some precision will be needed in this analysis. The following definitions are therefore submitted not because they are especially novel, but because the rigidity of concepts characteristic of investment analysis will facilitate revelation of the elements omitted by Mr. Keynes and by many other writers. References to their writings must, however, be restricted severely. Even the briefest examination of each of the many differences among concepts would expand the discussion of definitions to such length as to preclude a survey of the results that can be secured through the use of more accurate concepts.

In order to examine the phenomena significant for this purpose, all assets or property must first be divided into three classes: *money, products,* and *rights. Money* will exclude interbank and United States government deposits but will include all other demand deposits and currency in circulation except cash in the vaults of active banks. The significant distinction is, therefore, that between the next two items.

A *product* is any good such that its sale creates either income or ordinary revenue for some producer. Because of this resort to an accounting concept, products may be distinguished from other goods. These products include business inventories as well as the services rendered by men and by property. The purchase of a product by either business man or consumer advances the process of current production through one step.

Rights, as the term will be used here, consist of all assets not included within the definitions of money or of products. A house, when in the possession of some home owner, would therefore be a right; even though a few months earlier, if then in the possession of some speculative builder, that house would have been a product. To a home owner the selling price of his house would not be ordinary revenue.

Rights are of two kinds. (1) Some promissory notes give claims to goods not yet in existence. Borrowing in such instances may facilitate future production, but the sale of such notes does not necessarily enlarge the current output. (2) Other rights are claims on goods already produced. Though differences between these two kinds of rights are not significant in this study, it is important that both be included within the class called rights. For this and other reasons, the sum of the values of all rights may exceed the national wealth. Rights include the fixed assets of business and all goods owned by consumers as well as all securities and other evidences of investment, including all time deposits and savings deposits in banks.

Revenue funds consist of money which, while in the possession of its present owner, is available for purchasing products. Legally any dollar of money is normally available for any purpose that the owner desires; but folkways also are important in this connection. The concepts of capital and income affect the minds of property owners. Consumers frequently regard as revenue funds no more than the unspent portion of the last pay check or wage envelope. Business men, however, will properly regard as revenue funds all the money that they hold, except such portions as may have been accumulated specifically for sinking funds, the payment of bank debt or the purchase of securities. Money held to pay dividends, interest, rent or wages, as well as the money held to purchase materials and supplies, would of course be revenue funds. Such funds may be represented by the symbol R.

Capital money consists of money not now available for the purchase of products. Capital money is frequently available for purchasing rights, but immediate availability for the latter purpose forms no part of this definition. Because money held for one purpose cannot, however, be simultaneously available for other purposes, it follows that money held in order to purchase rights is necessarily capital money. Because dollars are identical in value, restrictions on the use of money apply to totals rather than to specific units.

Restrictions on the use of capital money arise in some instances from statutes. Banks, insurance companies, and financial institutions generally are restricted by law in the use of their money. A bank, for example, may buy the notes of a grocer; but it may not use its money to start a new grocery store. In other instances these restrictions arise from contracts or deeds of trust. The typical investment trust is free to buy the bonds of a steel mill; but it is not free to use trust money to build blast furnaces or to buy iron ore. Commonly, however, restrictions on the use of money arise from some owner's recognition of the difference between capital and income.

A man whose income is $500 a month may well own a deposit bal-

ance of $2,500. He may regard $400 of this amount as revenue funds available for current expenses. He may hold $1,100 available for investment as soon as the proper opportunity appears. He may regard the remaining $1,000 as a nest egg to be held permanently. If unexpected events compel him to deplete this nest egg, he will sell securities or strive in some other way to rebuild this balance to its predetermined magnitude. This $1,000 is itself his investment. In such a deposit, $2,100 would be capital money; but only $1,100 is now available for investment.

Capital money is obviously of two varieties. Much capital money is available for future investment. Available capital money may be represented by the symbol C_a. In many instances, however, capital money is held for other purposes. Some executor, if liquidating an estate for distribution, would probably not invest his funds even if offered an extremely attractive opportunity. Some investment banker may leave a large share of his total wealth permanently on deposit in order to facilitate occasional borrowing. Though the deposit balances of business should normally be regarded as revenue funds, the cash balances owned by financial institutions are normally capital money. Insurance companies, for example, invest most of their funds; but many of them seem also to have set certain minimum standards for their balances even though they do not borrow. People do the same. The individual in our example of the preceding paragraph held $1,000 idle as a matter of policy. Capital money not available for future investment may be designated by the symbol C_n to distinguish it from C_a, the capital money now available for investment purposes. C_n (capital not available) plus C_a (available capital money) equals C or total capital funds. The magnitude of C_n is apparently more stable than that of C_a. At a later point it will be necessary to recur to these two varieties of capital money; but at this point it is necessary only to note that both are included within the concept of capital funds. Relations between revenue funds and total capital money must first be examined. Four processes exist that may convert one of these into the other.

Financial saving consists of converting into capital funds money that has been received as income. This *saving of money* differs from the real saving. Real saving must be measured in goods. Real saving is an excess of production over consumption; but rising prices and incomes for some class may permit that class both to expand its consumption and to save money without expanding its physical output. Saving money implies that the source of funds is income recently received. Even though received recently, the source of such income is always past production. The essence of financial saving is therefore

restraint on current consumption and on the current demand for goods. Mr. Keynes is of course correct in pointing out that the saving of money, if no use is made of the money saved, diminishes production as well as consumption. Because producers are then less able to consume, it diminishes also future consumption and future production.

Financial saving is, however, not the only process that diminishes revenue funds. Real liquidation is on some occasions more important. *Liquidation* is the sale of an asset without replacing the asset. *Real liquidation* consists of (1) the sale of products to purchasers who pay for them with revenue funds, and (2) conversion of this revenue money into capital funds by the seller of such goods. If some department store replaces in its inventory only some fraction of the goods it sells, and uses $100,000 of its revenues to diminish its debt to some bank, then it has rendered this $100,000 unavailable for purchasing products. Bankers may or may not relend promptly the money they receive. While in the possession of bankers, this $100,000 is clearly capital funds.

Reduction of purchases by the department store in this example operates to diminish the total volume of current orders and of current production. Because producers' incomes are thus diminished, this real liquidation has diminished also the magnitude of future consumption and of future production. Until revenue funds are restored to their previous size, the demand for goods will necessarily be restricted. Differences between real liquidation and current concepts of disinvestment may be examined later. Real liquidation converts revenue money into capital funds and diminishes future output.

Real liquidation and financial saving are alike in their effect upon current and future money income. They differ, however, in their effect upon the nation's capital or wealth. Financial saving curtails consumption simultaneously with its curtailment of production. Though secondary effects may be more serious, the act of saving money does not directly diminish the nation's stock of capital goods. Real liquidation, however, affects production in advance of its effect on consumption. Production is checked by real liquidation and producers' inventories are diminished. Goods are transferred to consumers and are used by them in ordinary consumption. As consumers use up the goods they purchase, the national wealth (its stock of tangible goods or commodities) is diminished. If real income (goods) is contrasted with money values, such liquidation diminishes present real wealth as well as future money income. The extent of its effect on other magnitudes (real income and the dollar value of our wealth) depends on the behavior of prices.

Discrimination between saving money and real liquidation is now

easy. *Saving money,* financial saving, consists of converting revenue funds into capital money by methods that do not operate directly to diminish the nation's current stock of economic goods. *Real liquidation* converts revenue money into capital funds by methods that operate directly to diminish a nation's real capital as well as its future money income.

Conversions of revenue money into capital funds occur only in one of these two ways. A reverse flow, the conversion of capital money into revenue funds, is limited similarly to two processes. Expansion of revenue funds by any method expands, of course, the dollar demand for goods and expands therefore the money value of current and of future production. Such expansion enlarges the dollar magnitude of the national income in future years as well as in the current year. These effects on the national income will be reëxamined later. Differences among our concepts are more important at this point.

Investment is the use of capital money for the purchase of some asset. *Real investment* (perhaps the construction of a building) involves the collection of capital money (perhaps through a sale of securities), and disbursement of this money as revenue funds to people who assist in producing a new capital good. Some of the money, formerly capital, may be paid out to masons and carpenters as wages. By them it may be passed on in the purchase of ordinary consumption goods. Some of the money, formerly capital, may be paid out to the sellers of building materials who may use it to produce or to replace the goods sold. Two aspects of real investment should be noted. The money formerly held as capital is by the process of real investment made available for the purchase of products. In the second place, this money is no longer available for the purchase of securities. Some new act of saving or of liquidation will be necessary before it can again enter the securities market as a demand for bonds. Real investment enlarges revenue funds, but diminishes the funds available for lending.

Real investment stimulates production half a "cycle" in advance of its stimulus to consumption. The consumption-production cycle should be viewed as a circular flow of revenue funds. Though enlargement of revenue funds augments both production and consumption, nevertheless the point at which new funds enter or leave this stream is significant. Funds entering through real investment flow first through production and income payment before entering consumption. In the case of saving money funds flow through production; but they leave the stream before passing through the next consumption stage. It follows that, if money is saved and invested, the consumption stage of one "cycle" is omitted. It is this omission of one "cycle" of consumption that adds to the nation's wealth.

When real investment follows real liquidation, the consequences differ slightly. Real liquidation removes funds from the consumption-production cycle after consumption and before production. Real investment injects funds at exactly this point of departure. If time elapses between liquidation and investment, intervening production-consumption cycles will be on a smaller scale, at least in their dollar values, because the stream of revenue funds is smaller during this interval. Nevertheless, when real investment occurs and the stream is restored to its former magnitude, funds are injected at the point of their departure and no stages of a cycle are omitted. The world's supply of capital goods is therefore restored to its previous magnitude; but, if grocers liquidate and clothiers invest, the character of our assets may be altered.

The timing of real investment may differ from that of money savings. In this connection Mr. Keynes is right if he means to assert that real savings arise only at the time when real investment occurs. Real saving (the saving of goods) does not occur when money is saved. The saving of money checks production as well as consumption. Real investment, however, may create a period in which more is produced than is consumed. Real investment by one group (perhaps house builders) might of course be offset by current money saving or real liquidation among other groups (perhaps retail grocers); but a period in which revenue funds are expanding is necessarily a period in which compulsory real saving is enforced upon some consumers through enhancement of prices. The current stock of capital money can furnish funds for real investment even if expansion of bank credit, current saving and real liquidation were all lacking; but this source of capital money provides neither the facilities of production, nor the productive efforts that are also necessary. In spite of this lack, goods equal to the new investment are produced in excess of consumption during the process of investment.

Real savings, made compulsory by advancing prices, permit this adjustment of consumption. Mr. Keynes overemphasizes the importance of banking policy in his discussion of this point; but he notes correctly that (money) saving makes enhancement of prices unnecessary. Because he discusses only periods of net excess of investment, he can scarcely be criticized for his failure to recognize clearly that real liquidation (perhaps by lumber dealers) may supply the goods as well as the money used in real investment (perhaps by speculative builders).

Real saving consists of producing more goods than are consumed. Using the vocabulary suggested here, the half-cycles in which goods are produced without equivalent consumption occur only when real

investment occurs. Saving money causes unsold goods to pile up in dealers' hands only if dealers are willing and able to make additional real investment. The normal practice of business is to diminish production as sales diminish. Even if this policy were not common, and if dealers did permit inventories to pile up, it should be noted that these additions to inventory must be paid for. Such payment by dealers constitutes real investment. It is this necessity for additional real investment by producers when inventories expand that makes it obvious that augmentation of the nation's wealth arises only from real investment, not from the saving of money income.

Living on principal consists of using for consumption any money that has been previously segregated as capital. Capital money is acquired perhaps by the sale of a bond. This money is then paid out in consumption as revenue funds. The elements of living on principal are two: (1) capital money is converted into revenue funds, and (2) this is accomplished by a method that stimulates consumption at least as promptly as it stimulates production. Just as real liquidation is the opposite of real investment, so living on principal is the opposite of saving money. Financial saving by one family and living on principal by another would therefore simply substitute one set of consumers for another. The money value of a nation's income and the magnitude of its real wealth would remain unaltered.

Real liquidation by one person and living on principal by another would leave the nation's future money income undiminished; but such action would cause elision of the production phase of one "cycle." The national wealth would therefore be diminished to the extent of the goods liquidated by one person and consumed by another. If these goods were needed for production, future real income might be slightly smaller, and future prices might be slightly higher.

If the man who sells a security uses for consumption only that portion of the selling price which is profit to him, such living on principal is called usually the *spending of capital gains*. Because of inferential disagreement with the Brookings report,[1] this point should be expanded. The man who purchases a security uses necessarily money that is already available for purchasing rights. These are capital funds, whether the purchaser has borrowed them from a bank or has saved them himself. The seller of this security may subsequently divide his receipts into two parts. If one of these parts is treated by the seller as capital, the character of this portion of his money is not altered. If, however, the seller decides to use the second portion of his receipts for the purchase of goods he has by this decision converted some capital money into revenue funds. He has also created a demand for products

[1] H. G. Moulton, *The Formation of Capital* (Washington, 1935), p. 149.

that would not have existed otherwise. Consumption and production are both stimulated by his act. If the seller had held all his receipts as capital money, the total volume of consumption and production would not have suffered this expansion and the volume of capital money would not have been decreased.

Living on principal, when it is limited to the spending of capital gains, is peculiarly likely to cause an expansion of brokers' borrowings from banks. The spending of capital gains occurs frequently among stock-market speculators. Such speculators have usually an account with some brokerage firm. When a speculator desires to spend some portion of his gains, he asks his broker to send a check. A broker charges this disbursement to his customer; but such disbursement depletes also the broker's deposit at his bank. To replenish his balance, the broker borrows. Such borrowing expands both brokers' loans and normally the total of all bank loans on collateral. On the other hand, if a speculator saves money out of current income, he may use his savings to increase his margin at some broker's office. Such deposits by speculators expand the broker's cash and permit the broker to diminish his debt.

Alterations in the magnitude of brokers' loans arise then from financial saving and from living on principal. Such alterations arise also from other causes; but borrowings used to pay for securities will largely cancel out when many speculators are in debt. Money borrowed by a purchaser is transferred to a seller who may be forced to use it promptly to diminish his own debt because he no longer owns the collateral upon which his loan was based. Borrowing to pay for securities may thus fail to alter the magnitude of brokers' loans; but there is no such semi-automatic cancellation when money is withdrawn for real investment or for the spending of capital gains. Because some information is available with respect to the magnitude of real investment, data on brokers' loans furnish our best clue to the relative magnitudes of money saving and of living on principal among speculators. Rapid expansion of such loans suggests much living on principal.

Living on principal, real investment, the saving of money, and real liquidation all operate to alter the character of money. All four of these processes are also abnormal in the sense that alternative courses of conduct are more usual. Saving money is common; but use of revenue funds for consumption is more common among families, and use of such money for current production is many times more common in business. Living on principal occurs frequently; but living on income is many times more frequent. Real liquidation and real investment are of everyday occurrence; but the alternatives, to be described next, are far more usual. Because processes that alter the character

of money are abnormal in this sense, revenue money displays some tendency to remain revenue funds. Capital funds similarly, we shall find, display some tendency to remain capital.

The man who saves money may leave it for some time in his checking account. When he invests, he is more likely to buy a seasoned security than to purchase a newly issued bond. Sellers of seasoned securities are in turn more likely to buy other seasoned securities than to undertake real investment. Shifting of investments is common. Sales on the exchanges and elsewhere of seasoned securities may exceed greatly in magnitude the new issues distributed. The ordinary individual, unless he buys a new house, lacks usually the facilities for making real investment. Real investment has become almost exclusively a function of the business enterprise.

After several investment shifts some capital money may come into the possession of a person who will use it to buy a newly issued bond. Even then, conversion of such money into revenue funds is by no means certain. Corporations issue bonds in order to diminish current debt and to finance the transfer of existing assets. Owners who sell out their enterprises or fixed assets to some business combination would regard the proceeds of such sales as capital money. Mere transfer of corporate control, even in the absence of business combination, also involves frequently some redrafting of the corporate financial plan and the issue of securities. Men grow old, retire, and die. Their successors are normally younger and have less capital. Transfers are financed partly by personal borrowings; but they are financed also through the issue of new securities by the business that is being sold. Former owners of the issuing enterprise regard the money they receive as capital.

The purchase of a right is *paper investment*. Because money needed for family expenses cannot be used for the purchase of securities, rights are purchased only with capital money. Sellers of rights also regard the money received from such sales normally as capital. Few individuals when they sell a security use the proceeds for living on principal. Fewer still consider starting a new enterprise. Paper investment fails therefore to alter the character of money. Because many owners of securities lack either the capacities, the amount of capital or the time needed for successful real investment, money that has once been turned into capital displays always some tendency to remain capital money.

Paper investment may lead to subsequent real investment. The man who is saving to build a house might keep his savings in a checking account. He is more likely, however, to open a savings account or to buy seasoned securities. He thus transfers to others the capital money

formerly his. When he builds his house, he may borrow from some financial institution. The latter may thereupon replenish its cash by selling securities and thus acquiring capital money that others have saved or liquidated. The home builder will need also some equity. This he acquires by selling the securities he formerly purchased. He receives thus capital money that was saved or liquidated by others.

Stock exchanges have functions more useful socially than that of facilitating mere investment shifts. Even though securities may not be listed until after they have been sold by the issuing corporation, stock exchanges facilitate real investment by the owners of listed securities. Many a small grocer has without doubt financed the purchase of a new truck by the sale of Steel common or other security on some exchange. Many a corporation does most of its "borrowing" by selling some of the government bonds that it owns. In this manner it can secure the capital money of others without subjecting itself to the hazards of current debt. Exchanges facilitate also living on principal which may become highly desirable in periods of business depression.

Paper liquidation consists of the sale of a right without replacing this asset immediately by some other right or product. The money received from such sales was necessarily capital money to the buyer. By definition now it remains capital money when in the seller's hands. Though extensive paper liquidation may have secondary effects, such consequences are indirect. Paper liquidation, by definition, fails to alter the quantity of either capital money or revenue funds.

Paper liquidation, when conducted by a commercial banking system, is called credit contraction. If business men held capital money to the amount of their debts, credit contraction could occur probably without effect on production; but if business men had held capital money to this amount, they would have used it at once to pay debts without waiting for pressure from a banking system. Some business men may hold securities that can be exchanged without loss for the capital money of others, provided credit contraction by banks has not made capital money scarce also in the investment markets. Credit contraction is effective because normally it compels business men to secure additional capital money through real liquidation. It is this real liquidation that diminishes the dollar value of production and of incomes. It should be noted also that the unused lending powers of banks, if they were to be regarded as money, would necessarily be capital money.

Payment of debt is normally paper liquidation because it is a purchase by the borrower of a right formerly held by his creditor, and creditors may delay reinvestment to some extent. Real liquidation puts large amounts of capital money into the hands of business men.

Because interest charges are watched closely, real liquidation by business is followed promptly by paper liquidation. Business creditors include usually banks. Excess reserves in a banking system are therefore a normal consequence of real liquidation by business.

Disinvestment is an ambiguous term and should be abandoned. According to Mr. Keynes, it is the opposite of investment. Investment, he says on pages 74 and 75 of his *General Theory of Employment, Interest and Money,* might be restricted to the purchase of a security on some exchange, but should properly include the purchase of any asset "out of income." His concept of investment seems open to criticism on two grounds: (1) it fails to discriminate between real and paper investment, and (2) it fails to discriminate between ordinary purchases which use revenue funds, and investment which involves the use of capital money.

The ambiguity inherent in Mr. Keynes's use of the term has been developed for the worse by subsequent writers. It has been used on occasion to indicate any one of the following: (1) real liquidation, which diminishes the money income and the real wealth of a nation; (2) living on principal, which expands money income but leaves real wealth unaffected; and (3) paper liquidation which fails to affect directly either money income or real wealth. Since the acts that may be called "disinvestment" differ so greatly among themselves, it is suggested that this term be simply abandoned and more accurate concepts substituted.

Does the saving of money equal real investment? With these concepts in mind, it becomes obvious that the two processes could be rendered equal only by accident. The existence of business recessions indicates that the sum of money savings and real liquidation may on occasion exceed the sum of real investment and living on principal. An excess of living on principal and real investment over money savings and real liquidation would be evidenced by business revival. Obviously the total volume of revenue funds is not a constant.

Because revenue funds and capital money are both balance-sheet items, a technique for measurement is suggested below even though mere description of this technique reveals how inadequate is our present information and how inaccurate is any estimate based on this technique at the present time. For this purpose the relation of revenue funds to the national income must be examined briefly. If the exchange velocity of revenue funds (to be represented by V_r) is defined as the average number of times each dollar of revenue funds is transferred in a year, and if I_r is defined as the percentage of these payments that are income to the recipient, then the product, $R\ V_r\ I_r$, because of these definitions is equal to the national income paid

out. Obviously also the product of V_r and I_r is an income velocity of revenue funds. Separation of income velocity into its two components is, however, useful here.

Variations in the exchange velocity of capital money (V_c) may perhaps be limited only by the choices of owners of such funds, and the exchange velocity of such money may therefore be highly variable. Variations in the exchange velocity of revenue funds, however, are limited by more tangible elements. The wage-earner must make his revenue funds last normally until the next pay day. Some farmers must make their revenue funds last until after the next harvest. Business men are less restricted; but in many industries there are standards as to the amounts of cash required to handle a certain volume of business, and a trade "service" tabulates such information annually for the lending officers of banks. Exchange velocity in such industries is not constant. Alterations of business policy, alterations in the structure of business, and alterations of the direction in which income is spent all affect presumably the velocity of revenue funds (V_r); but for any brief period the range of variations in this average velocity may well be more restricted than the range of variations in the average velocity of total money. If V_c is much smaller than V_r (perhaps in 1941), then variations in the exchange velocity of all money may arise solely from variations in the relative magnitudes of revenue funds and of capital money without alteration of the exchange velocity of either. The point immediately significant is that variations in the exchange velocity of total money do not necessarily indicate equally large variations in the exchange velocity of revenue funds.

The payments of revenue funds that are income to the recipient form a variable percentage of the total payments made by use of revenue funds. Seventy per cent of the payments made by some railroad may be income to the recipients. In some wholesale establishment, on the other hand, this percentage may be as small as ten. Alterations in the structure of business and alterations of the direction in which consumers spend their incomes could cause large changes in the magnitude of I_r; but changes of this kind, if large, are not likely to occur suddenly. Alteration of profit margins and of the percentage of profit paid out could, however, cause this ratio to be altered quickly.

Business prosperity and the expansion of business volume tempt business men to turn over their cash more rapidly; but such periods operate also to expand profit margins and to diminish the percentage of profits paid out. Examination of financial statements reveals that, when business is improving, V_r tends to expand and I_r to contract. When business volume is diminishing, business men hold more cash relatively to sales; but business profits are decreased and out-pay-

ments of income tend to become a larger percentage of business revenues. During business recessions V_r is diminished, but I_r is increased. The income velocity of revenue funds (V_r I_r) is apparently more stable than either of its components. It seems quite possible that the income velocity of revenue funds may well be more stable than the income velocity of total money.

In the calculation presented below, it has been assumed that the income velocity of revenue funds remained constant for several years. Such absolute constancy is of course improbable; but in the present state of our knowledge the use of any other assumption would be even more unwarranted. Use of this assumption makes possible an illustration that will both clarify and shorten the description of certain additional attributes of these functional classes of money. The illustration used here covers the years 1929-1939. In addition to cyclical causes of variations in V_r I_r, the growth of government expenditures for relief after 1932 may have altered the direction in which the national income was spent so greatly that the value of V_r I_r was affected perceptibly. After 1939 the growth of armament expenditures introduced a further element that might affect V_r I_r. In general, each year that comparison is extended, increases the probability of significant variation in the income velocity of revenue funds. It is believed, however, that variations of V_r I_r during the period 1929-1939 were not great enough to render this illustration misleading for the restricted purposes for which it will be used here.

In order to estimate the magnitude of capital funds in 1939, it is necessary to start with 1929. This is the most recent year with respect to which we have reason to believe that capital funds were substantially exhausted. Six years of rapid real investment had been followed by a year in which realized capital gain reached an estimated magnitude of about 6 billion dollars, and real investment was then supplemented by the spending of some portion of these gains. Brokers' loans and total bank loans on collateral became greatly expanded. Even an enormous initial stock of capital funds, if available in 1922, might well have been depleted by the fall of 1929. During the latter year also the sale of new bond issues became difficult.

The most convincing evidence of a shortage in 1929 of available capital money arises, however, from a different source. Small recessions in the prices of stocks ceased to attract significant increments of capital funds into the market. Recession of security prices became more rapid—again without attracting adequate additional capital funds. Because investors had been exceptionally confident during the earlier months of 1929, it seems possible that the market supply of C_a offered at the rates of yield current in mid-summer may well have included

substantially all the capital funds then available for investment at any rate of yield. Supply of capital money had certainly become inelastic. In the fall of 1929 the supply of capital funds had apparently also reached its minimum. An alternative explanation—that investors increased their liquidity preferences at this time both suddenly and by large amounts—would suffice only if this change of heart affected substantially all investors simultaneously; but if C_a were indeed depleted, then relatively small amounts of paper liquidation, real investment, or living on principal could force rapid recession in the prices of securities.

Minimum capital money does not imply that all money had become revenue funds. Even if purchases of securities were paid for in some instances by money derived from sales made in a subsequent hour, still some volume of C_a was necessary to finance investment transactions. This volume may have been small. Because a broker combines the cash of all his customers into a single account, the use of brokers diminishes the total need for capital money. Organization of the Stock Clearing Corporation in 1919 resulted in further economy of the money needed to finance transactions in securities. Professor Huebner has indicated that the cash actually used by brokers in New York during 1929 averaged less than one-fifth of the daily transactions. As a percentage of the year's business such an amount of capital money is trivial indeed.

Capital funds, however, include C_n as well as C_a. A prolonged period of expanding income may be expected to enlarge the amount of money held as an investment and not available for current purchases of securities; but rising prices in the securities markets may cause alterations of investment policy and may thus diminish C_n. Financial institutions that publish statements of condition held in 1929 balances that seem small by present standards. A small survey limited to personal acquaintances suggested strongly that the volume of capital funds held by individuals was also small during the autumn of 1929.

For these reasons a magnitude of only 5 billion dollars has been assigned to total capital money for the year 1929. This estimate, it should be emphasized, is no more than a somewhat painstaking guess. Its error may be sufficient to invalidate its use for any purposes except those for which it will be used here. If 5 billions, however, were the magnitude of total capital money in 1929, then revenue funds in 1929 amounted necessarily to 23.3 billion dollars.

By definition also, $R\ V_r\ I_r$ equals income paid out. Substituting now in this equation the Department of Commerce estimate for income paid out (81.65 billions), we find that the indicated income velocity of revenue money for 1929 was approximately 3.51 per year. This

estimate differs from Professor Angell's figure for "circular velocity" in the right direction and perhaps by about the right amount. By assuming—and this may be the more dangerous assumption—that income velocity remained constant for the next ten years, the following values were derived. In the following table M is money in circulation outside of banks; M^1 is demand deposits exclusive of those of the United States and interbank accounts; R + C is total money, R is the amount of revenue money as indicated by the calculation suggested above; C or capital money is—except for 1929—a remainder found by subtracting revenue funds from total money. C_1 (the cash held by life insurance companies) is appended for comparison. Results are quoted only to the nearest tenth of a billion dollars.

Year	*M*	*M*¹	*R* + *C*	*R*	*C*	C_1
1929	3.9	24.4	28.3	23.3	5.0	.1
1930	3.7	24.1	27.8	21.3	6.5	.2
1931	3.9	21.3	25.3	18.1	7.2	.2
1932	4.9	16.4	21.3	14.1	7.2	.3
1933	5.0	15.2	20.3	13.3	7.0	.5
1934	4.7	17.5	22.2	15.4	6.7	.6
1935	4.8	21.6	26.3	16.7	9.6	.8
1936	5.2	25.4	30.6	19.4	11.2	.8
1937	5.5	26.9	32.4	20.7	11.8	.7
1938	5.4	25.9	31.3	18.9	12.4	.8
1939	6.0	28.9	34.9	19.9	15.0	.9

Business recession is presumably a period during which capital money is augmented. During the years 1929-1931, real liquidation by business coöperated with the saving of money income to curtail revenue funds and to expand capital money; but credit contraction by banks wiped out much capital money and bank closings destroyed revenue funds as well as capital money. Future corrections may alter the magnitudes reported above; but collateral evidence supports the conclusion indicated by these estimates. In spite of credit stringency among banks, the nature of the investor's problem had been altered by 1931. Lack of capital money was no longer his chief difficulty. Liquidity preference or lack of investment confidence was a more significant element in 1931 than in 1929.

During the years 1932-33, however, credit contraction and bank closings proceeded so rapidly that capital as well as revenue money money was diminished. Ordinarily business recession, because it involves real liquidation, may be expected to provide the capital money (as well as the excess bank reserves) needed for financing subsequent business expansion. During 1932-33, however, so much of the capital money created by business liquidation was subsequently destroyed by

bank liquidation that the amount of capital money left available in 1933 for financing business revival was inadequate to finance substantial recovery. In 1933, then, good reasons existed for increasing bank reserves and for facilitating credit expansion by banks. The conclusion to be drawn from the estimate for 1933 agrees then with established opinion.

During the year 1933-34, the money created by credit expansion was absorbed rapidly into revenue funds. A diminution of capital money is also to be expected in a period of greater real investment and living on principal.

One aspect of the year 1934-35 deserves especial comment. Granting the limitation on total consumer demand that is implicit in the concept of an income velocity whose variations are limited by tangible forces, it follows that a business revival with its expansion of revenue funds may be prevented by an excessive general level of prices as well as by a faulty price structure or other elements. If revenue funds of 23 billion dollars were needed in 1929 for normal production at the prices current in 1929, and if the variations of income velocity (V_r I_r) are limited substantially by tangible elements, then revenue funds of 15 billion dollars in 1934 could facilitate a similar physical output only if the prices charged to consumers had also fallen approximately in the ratio 23 to 15, because revenue funds must pass through consumption as well as through production. Since the average price of finished products in 1934 exceeded the level established by this requirement, there was presumably a price-level obstacle to business investment in addition to such obstacles as may have arisen from other causes. Until 1936 the volume of revenue funds was inadequate to permit full employment of productive facilities at the prices then current. When existing facilities are not utilized, business men have little reason to undertake real investment. If commodity prices and construction costs are both abnormally high relatively to consumer income, then housing construction may be curtailed with especial severity.

Revenue funds, expanded largely by government activities, attained approximate adjustment to the price level in 1936; and approach toward this adjustment may well have facilitated the business expansion of that year. Business liquidation in the year 1937-38 must then be explained on other grounds, such as a disproportionate advance of wage rates or events in Europe. Though the gigantic subsequent magnitude of capital money may raise practical problems, the events of 1934 and of 1937 are more significant here. Approach to the problems of real investment through a use of the concepts presented here,

though it tends to emphasize the significance attached to a general price level, does not diminish the importance assigned to the internal structure of a price system.

Even though the estimates presented above may suffer future correction, this illustration has indicated the behavior that should be expected from capital and revenue money. It suggests also the possibility that at some time a technique may be developed which will measure the relative importance at different periods of the various obstacles to real investment, such as a scarcity of capital funds (1929), liquidity preference among business men and investors (1931), an excessive general level of the prices demanded from consumers (1934), and a faulty internal structure of the price system (1938). Among the forces that affect the national income directly, there is a noteworthy lack of any good index of living on principal by nonspeculative investors.

In the March and June issues[2] of this journal Dr. Mordecai Ezekiel presented measures of saving, consumption and investment. To any one familiar with the difficulties in this field his achievement is impressive. His measures of consumption and investment are extremely valuable; but he measures saving by measuring "offsets to saving" on the hypothesis that "in any one year total investment equals total saving."

This common idea that financial saving is equal to investment seems to be based solely on a pun. Saving, the process, is confused with one result of financial saving; namely, capital money left in the possession of savers. The moment one trains one's self to call this result by a name different from that applied to the process, it begins to be obvious that the process of saving money has also other results and that nothing tangible is created by the saving of money income.

Dr. Ezekiel's "offsets to saving" consist of real investment minus real liquidation plus the more measurable portions of living on principal. He cannot be criticized for his failure to complete the measurement of living on principal. That process appears often in forms that defy present statistical controls. His error, if it may be called such, is his assumption that the amount of capital money remained constant throughout the period 1921-1940. The amount of capital money is, however, highly variable.

The error created by substituting "saving" for "offsets to saving" is of course less than the 10 billion dollars by which capital money was increased during the period 1929-1939. Total money was expanded by 6.6 billions during this period, and a large share of this new money

[2] *Statistical Investigations of Saving, Consumption, and Investment:* Part I, *Am. Econ. Rev.*, Vol. XXXII (Mar., 1942), pp. 22-49; Part II, *ibid.* (June, 1942), pp. 272-307.

became capital funds. Errors resulting from the use of a constant value for $V_r I_r$ in the sample calculation presented above may also have been large; but evidence of many kinds indicates unmistakably that money savings in 1929-1939 exceeded "offsets to saving" during that period by several billions of dollars. The savings that were not absorbed by "offsets to saving" expanded the cash balances held by life insurance companies in 1930-1940 by 896 million dollars. Such savings enlarged also the balances held by other institutions and expanded to unprecedented magnitude the idle cash held by private investors. Because of the nature of present investment processes, such individuals are almost necessarily the principal owners of capital money.

PRICE CONTROL AND RATIONING

SOME ASPECTS OF PRICE CONTROL AND RATIONING[1]

By W. W. Rostow

I. The Fall of Selective Price Control

The freezing of retail prices, on May 18, 1942, brought to an end the period of so-called selective price control. In September 1940 when efforts at price control were first informally begun, there were already those, marked by the experience of 1917-18, who advocated a general freezing of prices and wages. The majority of economists, however, opposed such wide and drastic action at that time. The impact of the armament program was still extremely uneven, and it was felt that price and wage increases in certain areas might usefully serve to redistribute resources and to stimulate output, at least up to the level of current fixed capacity. Control was instituted in those individual markets where existing and anticipated war demands were most strongly felt and where substantial price increases had already taken place—at first largely metals and metal products, and lumber. During the year 1941 most of the basic materials, other than farm products, and some semi-fabricated and finished goods, were brought under control.

Between February and December 1941 some 45 formal price schedules were fixed. In December 1941 and January 1942, with the sharp acceleration in production and production plans, 42 schedules were required. In the year ending January 1942 the average monthly increase in wholesale prices was at a rate of 1.7 per cent; in the month after Pearl Harbor, at a rate of 2.6 per cent. Retail prices rose even more rapidly. The control of prices through individual markets was no longer feasible.

Broadly, then, history will regard selective price control as the instrument more or less appropriate to the early stages of rearmament, the

[1] Editor's Note: This paper was presented to the *Review* by Professor Edward S. Mason, chairman of the Conference on Price Research, with the following note: "The annual meeting of the Conference on Price Research at the National Bureau of Economic Research, May 8, 1942, was devoted to a discussion of general maximum price control and of rationing. The speakers at the conference were Donald Humphrey, Hans Neisser, Paul O'Leary, Harold Rowe and Richard Gettell of the Office of Price Administration, and A. F. W. Plumptre of the Canadian Legation in Washington. This paper is a condensation of the remarks and discussion and was prepared by W. W. Rostow, Office of Strategic Services."

universal price ceiling and rationing as a concomitant of the full war effort. The rough justice of this view should not, however, conceal the particular forces which necessitated the abandonment of selective price control; for, in itself, the "freeze" does not guarantee their easy regulation.

Under selective price control prices representing roughly half the productive activity of the economy were, at various dates, frozen at the wholesale level. These were, for the most part, prices of widely used industrial raw and semi-manufactured materials, and industrial equipment. It was hoped that industrial costs, in general, would be held in check by the stabilization of these prices.

At best, this method promised to limit the rise in certain categories of industrial costs. There was no control of farm prices, and rising foodstuff prices intensified the pressures, in an otherwise tight labor market, for higher money wages. Government contracts, replete with escalator clauses, were being let at unit prices which failed to take account of the cost-reducing consequences of large-scale production. And, on the side of demand, no serious effort was made in our fiscal policy to limit incomes to a level commensurate with the supply of goods available at current prices. In this setting, the controlled prices held, but the uncontrolled prices continued their steady rise.

As conceived by its advocates selective price control was never regarded as a sufficient device. Under the protection of adequate fiscal and wage policies, and with a free hand in selecting the prices to be controlled, it might have succeeded in controlling the price structure as a whole and adjusting and guiding it to meet the accelerating pace and changing character of the war effort. The Treasury did not, or perhaps in the nature of the political atmosphere could not, accept its central deflationary rôle in such a scheme; while other political forces limited the extent to which controls might be applied to money wages and to farm prices. Selective price control in practice was, therefore, neither the reflection nor the testing of a general theory so much as an opportunistic compromise. Pearl Harbor was required to give shape to our economic as well as to our military policies. When, early in 1942, the Office of Price Administration found itself virtually administering an inflation, a more powerful and direct instrument of control was necessarily invoked.

II. The Freeze

The freeze order is distinguished from the earlier procedures not only because it is general, but because it brings its pressure to bear at the retail as well as at the wholesale end of the price structure. The theory of its operation is, simply, that the business man can no longer look

to Washington and upward adjustments for relief. The ceiling is fixed. Under it, the retailer, the distributor, the wholesaler, and the manufacturer must, in general, find their own salvation. Official relief can not take the form of price increases; only a selective dispensation of subsidy remains.

The freeze order thus has the central advantage of breaking the cumulative circle. A pressure from the side of costs must, in the typical case, be resolved in the market for factors of production where it originates. Ideally, it can not be transmitted.

This new relationship based on a fixed outer price limit is, of course, of special importance as a means of halting the rise of wage rates. The persuasive case for a stabilized level of wages could only be made when the rise in the cost of living had been checked. It was, in the nature of labor's experience, impossible to curb the agitation for higher money wages in the face of rising retail prices. That kind of real wage reduction was not tolerated; whereas a reduction engineered through rationing, taxation, and forced savings, within the framework of fixed retail prices, enjoys a reasonable opportunity of popular acceptance.

III. Gaps in the Freeze Order

It seems doubtful, however, that the price freeze is going to cause unemployment, or even a material shortening of work hours among the price administrators. In the first place, the freeze order in its present form is not complete in its coverage. It has three major gaps. About 29 per cent of the food component of the cost of living, and 20 per cent of wholesale food prices are uncontrolled; this leaves an estimated 13 per cent of the cost of living outside the jurisdiction of the order.

Secondly, no formal provision has been made for the control of money wage rates. Opinion differs as to the seriousness of this omission. A number of forces are operating in such a way as to facilitate labor self-restraint: the retail price freeze, the pressure of patriotic appeal, the announced stabilization aim of the President and the War Labor Board, and the narrowing range of possible consumer expenditures. A surplus of cash has characterized the wartime condition of both British and German working men. On the other hand, as the Canadian experience indicates, many employers may find themselves able and willing to countenance higher money wage rates. Unless effective steps are taken to control labor mobility, a competitive bidding up of wage rates may add to the burden of the price problem in both its fiscal and administrative aspects.

The danger of voluntary wage increases is reinforced by the third

major gap in the price control order. Government contracts have not yet been subject to formal regulation. Some contracts contain escalator clauses that permit the automatic transfer to the government of cost increases. It is too early to measure the importance of this factor. The current tendency is, in fact, to re-negotiate contracts at lower unit prices, in somewhat belated recognition of the economies of capacity output and of large-scale production. Nevertheless, a way remains open for bringing abnormal competitive pressure to bear on producers who are not able to transmit wage increases to their consumers. The use to which the escalator clause is put clearly demands vigilant and critical scrutiny.

IV. The Squeeze and the Roll-Back

As noted earlier, a readjustment of cost-price relationships within the framework of a retail price ceiling is intrinsic to the price order in its present form. Among the groups affected the retailers have been subject to a special pressure. This pressure—the squeeze—arises because some retailers were selling, on the base date, at prices based on the cost of goods purchased at an earlier date and not on a replacement cost basis. If all retailers were, on the base date of the general ceiling, setting prices on a replacement cost basis, there would be no squeeze. In fact, no special problem exists in the case of eggs, meats, and other nonmanufactured foodstuffs which have a short period of turnover. The squeeze is, of course, most severe in the case of manufactured goods, a considerable inventory of which is normally held in stock.

The general theory of the freeze order is that the Office of Price Administration, aided by the natural pressure from the retailers, should take the initiative and force wholesalers and manufacturers to lower their prices in such a way as to reëstablish normal cost-price relations throughout the economy. A nadir in Washington administrative jargon was reached when this process was called "rolling back the squeeze." To the extent that the pressure from the retailer succeeds in forcing a general downward adjustment in the price structure, retailers eliminate a major burden for the administrators. They are, in any case, placed in the position of having a heavy vested interest in resisting any upward creep of prices on the manufacturer's or wholesaler's level.

It is of the nature of a modern war economy that the retailer and distributor, in general, must suffer. In the case of automobiles and other durable consumers' goods decimation has already occurred. The problem of dealing with such instances is essentially independent of the price freeze order. But where a lowering of prices at the manufacturing stage is impossible, and where bankruptcy can not be countenanced, subsidies

may be required. An effort has been made to measure the maximum sum that might be involved in supporting by subsidy the retailers' position. It is estimated that wholesale prices would have to be lowered by about 3 per cent to eliminate the present squeeze on retail prices: that represents the net lag of retail behind wholesale prices from June 1939 to March 1942. Excluding meats and nonmanufactured foods, assuming that retail prices are fixed by means of a constant percentage mark-up and that the roll-back will not operate, this might involve annual subsidy payments of the order of 600 to 700 million dollars, if the retailer's profit position were to be maintained.[2]

This figure has been confirmed, as an outside limit, by an independent calculation. The average turnover period, by type of retail store, was established as of 1939. The testimony of retailers indicated that inventory costs were taken as an average of original and replacement cost. The lag could, therefore, be expressed as one-half of the turnover period. On this basis the sum necessary annually to compensate for the squeeze was calculated by type of retail outlet. It came to 650 million dollars.

In fact, outlays on this scale are not likely; because (1) some roll-back can be expected; (2) a considerable proportion of the retailer's costs are fixed, and a mark-up proportional to the rise in wholesale prices would not be required to maintain the retailer's net income; (3) the absorption by some retailers of a part of the squeeze may be possible without endangering their solvency, in the present state of reserves and profits; and (4) the subsidy will not, in fact, be used to maintain all retailers in business. The problems facing the administrators are likely to be problems in special markets and special regions. The freeze procedure in itself is not calculated to convert the retail trade as a whole into a distressed area.

A special and important case of a not dissimilar lag is that of money wages. A part of the hesitancy on the part of the government to establish formal wage ceilings may well have stemmed from a fear that the fixing of March retail prices might involve some general discrimination against labor. On the whole, however, the wage rises in coal, iron, and other basic industries, in the course of 1941, are believed to have established a situation which will permit the acceptance by labor of the March range of retail prices if that level of retail prices is, in fact, held. Some upward adjustments, in certain of the labor markets, may be required, and have, in fact, occurred since the freeze order. But if the wage agreements in the major war industries can be maintained, it is possible that labor's dissatisfaction in the course of the war will not take the form of a general demand for higher money wage rates.

[2] It is worth emphasizing that not only the retailers themselves, but also landowners and municipalities have a substantial vested interest in maintaining solvency in retail trade.

V. Quality Deterioration—Implicit Inflation

A difficult, but not necessarily dangerous problem is raised in the administration of the price order by the deterioration in the quality of manufactures which is already under way and which can be expected to become more acute. The refined and various output of our pre-war industrial machine yielded, in each market, a complex array of similar goods of differing quality, sold at different prices. The clothing trade offers, of course, a prime example of this complexity.

As quality deteriorates it is unlikely that, on their own initiative, retailers will concomitantly lower prices. An extra profit for the retailer, or a profit shared throughout the chain of relevant markets, results. To the administrator this windfall is not a major threat; since it produces no direct pressure against the price ceiling. It involves a cut in real income for the community, and enlarged business profits. The OPA can, of course, exert formal and informal pressure for retail price reductions at the manufacturing and distribution levels; but the issue is likely to remain peripheral. Perhaps the best solution is the development of standardized and uniformly priced products over a wide range of consumers' needs.

VI. The Price Freeze and Production

Selective price control, as a concept, envisaged the use of the price mechanism as a means of stimulating production in the directions which the armament program indicated as desirable.

There is some doubt as to the extent to which OPA policy, prior to the freeze, positively contributed to increased war production; but it is evident that selectively controlled prices forced no large number of necessary producers into bankruptcy. To the extent that prices remained free to fluctuate in response to war demands, the rough purposes of the war program, at that stage, were served.

The price order, however, arbitrarily freezes the price structure at a given moment in time. Should the requirements of the war effort alter, it inhibits a price increase from evoking automatically a desired increase in production. In an otherwise uncontrolled economy, a price freeze would, undoubtedly, have important and probably undesirable effects on the allocation of resources. The power of subsidy, however, as recently employed in the case of scrap rubber, avoids the principal danger inherent in this situation. The presence of Mr. Henderson in the War Production Board affords the possibility of a unified production policy, in which subsidies play their part, along with priorities and direct allocations, in achieving the desired disposition of resources. The

problem posed by a rigid price system faced with shifting tastes and demands is more likely to arise in some future planned economy than under the direct controls of modern warfare.

VII. Rationing and the Freeze

The freezing of retail prices represents a decision on policy with respect to one of the three major variables that will determine the distribution of civilian goods during the war. In general, the problem of distribution is one of matching the supply of goods and the flow of spendable income, at a desired price level, and of absorbing (or neutralizing) the residual fund of spendable cash in consumers' hands. If this process is fully to be controlled, closely interrelated decisions must be taken with respect to price levels, appropriate allotments of relatively scarce goods, and the removal (or neutralization) of excess funds in the consumers' goods markets. In fact, distribution is not fully controlled in the United States. Nevertheless, control measures in each of these three directions have been taken.

Prices are now being held to maximum levels lower, in many cases, than those that would obtain if consumers were free to compete for scarce supplies of goods; and the rationing of certain scarce individual commodities, on some socially equitable basis, has been attempted. Finally, taxation sufficiently severe to narrow substantially the inflationary gap is being sought.

VIII. The Case of Sugar

Rationing has thus far been confined to cases where the special conditions of the war have substantially reduced current supplies: notably sugar and gasoline. The case of sugar, where rationing policy and procedures appear to have been fairly well stabilized, reveals many of the problems that will characterize other rationing efforts; although, of course, the sugar market is, in many ways, distinctive.

1. The Point of Initial Control

A primary rationing problem is to establish control over the flow of supplies at that point in the market which presents the least administrative difficulties. In most cases that point occurs where the market is narrowest; *i.e.*, where the smallest number of operators handle the total supply. In the sugar market control was established at the point of import for direct consumption sugar, and at the point of refining in the case of beet and cane. The importers and refiners must account for all sugar sold as direct consumption sugar, either by turning over the

instruments received in connection with the rationing to civilian users, or accounting for it as having been sold to the government. They are the final collectors of the coupons of civilians and the allocation certificates of industrial consumers of sugar.

2. Initial Stocks

The ability of the wholesaler or retailer to secure supplies depends on his surrender of coupons or certificates. The amount of these available depended in large part on the stocks of sugar held when rationing went into effect. Those who held no stocks would, in effect, be out of the market for the duration. Those with excessive stocks were at a great competitive advantage. To meet this situation an effort has been made to adjust distributors' stocks to a level meeting the needs of his normal turnover. Sugar stocks have not been physically transferred; but, for a time, allotments have been made on a selective basis, designed to produce a roughly uniform relation between stocks and the normal volume of sales. With this adjustment the sugar allotments can be employed as a useful measure of the distributor's importance in the market as a whole; and future food rationing allotments may be made on the basis of the present flow of sugar through the various retail and wholesale outlets.

3. The Determination of Total Supply

A delicate question that had to be answered before civilian or industrial allotments could be made was the size of the flow that could be expected over the immediate and middle future. Ideally, for those charged with rationing, this figure should be a given, determined by the WPB. The OPA can only serve as the administrative middleman, distributing with minimum friction the supplies available after the more urgent but capricious demands of the war effort have been satisfied. Even in the case of commodities grown or manufactured within the United States, a supply figure guaranteed to hold over any considerable period of time can not be furnished by the WPB. In the case of sugar the problem was accentuated by the partial dependence of supply on imports and shipping allotments. It is clear that the figure for supply, on which the initial rationing periods were actually based, was something of an approximation.

4. Civilian and Industrial Allotments

The mechanical problem of designing and printing ration books and of mobilizing a staff for civilian registration was, of course, enormous. Nevertheless, that aspect of the task, and the gaining of public acceptance, proved relatively tractable. More serious difficulties arose with

respect to allocations for institutional and industrial users. As the pilot commodity in the field of food rationing for household consumers sugar was eminently satisfactory. Its wide commercial and industrial use, however, introduced numerous complexities.

Among other uses sugar is employed in the tanning of leather, the manufacture of powder, and the feeding of bees and canaries. In some uses the product to which sugar contributes is of greater importance, under present conditions, than sugar itself: in canned meats, preserved fruits and vegetables, canned milk, and so forth. In such cases sugar was allotted for all units of the desired product available. Efforts have been made to induce economy in such uses, but no vegetables or meat will rot for lack of sugar.

Restaurants and institutions have been allotted 50 per cent of their usage in the corresponding months of 1941; or, to take account of the large turnover in restaurant ownership, March 1942 may be used as the base for all months. All other users have been allotted 70 per cent of 1941 consumption rates: bakers, confectioners, bottlers of soft drinks, and so forth. Rationing of this category has revealed strikingly the extent to which the public is attached to different manufactured foodstuffs. The cut in sugar allotments to bakers has caused little complaint; restrictions on bottled drinks, however, have created real difficulties. The speed-up of industrial operations has entrenched the mid-afternoon Coca-Cola as a national institution.

5. Special Adjustments

Two residual problems of considerable importance are the supplying of supplementary sugar allotments to expanding defense areas and to housewives for home canning. In many rapidly growing communities restaurants, hotels, and other institutional consumers are springing up; and in most cases their demand is legitimate. Further, the local bottlers of soft drinks, with allotments based on pre-war consumption, have found themselves unable to meet requirements. The working out of satisfactory adjustments has proved a complex administrative problem. Similarly, the use of sugar in home canning is clearly of high priority; but the elaboration of a system of supplementary rations, representing a minimum compatible with the avoidance of spoiled fruits and vegetables, will not be an easy task.

6. Equating Supply and Demand

In a sense, the experience of sugar rationing offers a partial answer to the old academic controversy concerning the possibility of fully planning the operations of a given market. The practical as well as the theoretical resolution appears to be a method of trial and error. Neither

supply nor demand, under the conditions of the experiment, was exactly known. Presumably the allotments for the first rationing period were set conservatively, in the light of expected supply, with the expectancy of either achieving a net increase in stocks at the end of the period, or a more or less exact balance between the current flow of supplies and current consumption. It was realized, however, that many of the data upon which this informed series of guesses was made might change; and in fact they did change, notably with respect to the shipping situation. But a close scrutiny of the mass of evidence pouring in to the administrators should supply a basis for immediate adjustment of unit allotments or of rationing periods, if that is desirable; and, over a period of time, their experience should yield an increasing sense of the magnitude of the variables that determine supply and distribution in the markets for sugar and other foodstuffs.

7. Block Rationing

The distribution of sugar was set up in such a way as to permit an easy extension of rationing to other scarce foodstuffs. The experience of both the public and the administrators with the problems of sugar will, surely, facilitate the rationing of other commodities in this field. The extension of rationing will, however, almost certainly involve dealing with some commodities less homogeneous than sugar. Sugar's virtual uniformity in quality and, so far as noncommercial rationing is concerned, singleness in form helped make it an ideal pilot in the field. In the case of (say) canned goods or meats a more complex system of points will have to be worked out. Within the field of canned goods, for example, prices may be quoted in points as well as in money terms; and within his total point supply the consumer may exercise a certain independence of choice. Changes in consumers' tastes can be easily met by an adjustment of the point-prices attached to the various commodities. In this way, it is envisaged, rationing can flexibly expand—commodity by commodity, block by block—under the probable gradual tightening of supply conditions.

IX. The Rationing of Apparel

It is possible that at some stage of the war effort civilian clothing will have to be rationed. The complexities of this potential problem emphasize the relative simplicity of rationing sugar. Clothing is heterogeneous; it varies in quality; the demand for it varies with age, occupation, locale, and season; it is manufactured by numerous firms; and it is semidurable. From these characteristics stem the major difficulties in any system of clothing rationing.

1. The Problem of Timing

It is approximately ten months between the time a mill begins weaving and the time the finished garment appears at retail. This lag between the flow of raw materials and finished output affords a useful interim to those who may be called upon to institute the rationing of apparel. If rationing were introduced immediately upon the appearance of a raw material shortage, the various stages in the market would hold substantial stocks capable of cushioning the supply situation, and of permitting a fairly general type of rationing. If rationing were permitted to await the appearance of shortages at the retail end, it is likely that the administrators would be faced with the interminable problems of selective rationing: according to age, occupation, and so forth. A general point system, with occasional exceptions, might be impossible.

The semi-durable character of clothing requires, further, that the planning of rationing be done with real secrecy; and that the procedures be introduced virtually without warning. At worst, the hoarding of sugar in anticipation of rationing, caused stock-piling by some individuals of a few weeks' or months' supply. Even this amount of hoarding proved largely correctable. A run on the clothing stores, however, many of which are swollen with stocks, might involve the purchase of a supply for a year or more by a sufficient number of persons to affect the whole basis of the rationing scheme.

2. Some Problems of a Point System

It would be all but impossible to apply a point system to the full range of apparel available in the pre-war clothing market. Differences in style, service, quality, and type of garment involve degrees so fine that a money price system is required fully to reflect the shadings. The distinctions are such that it would be impossible even to define the various grades of clothing within the retail markets, in formal administrative terms. The European experience has been that standardized garments, for large-scale consumption, were a necessary condition for successful rationing.

Almost any rationing system, even for standardizing garments, must take account of the needs of special groups in the population. The wide range of American climate; the requirements of the heavy worker, of children and expectant mothers—all these and other legitimate distinctions promise the potential administrators elaborate difficulties, especially if the total supply situation has badly deteriorated by the time rationing is introduced.

The actual construction of a point system for clothing involves, in simplest terms, the allocation of coupons just sufficient, over the neces-

sarily long rationing period, to absorb the supplies available. Initial information, both as to the size of clothing stocks and consumers' habits, is even more unsatisfactory than in the case of sugar. It is believed that, at the retail, wholesale, and manufacturers' level, there are very substantial stocks of clothing; but it is evident that they are distributed very unevenly. Some sellers have rented warehouses, others are already in short supply. A reallocation of stocks in the clothing market is certainly not as tractable a problem as in the case of a single homogeneous commodity, such as sugar.

The apparel industry, in fact, is not a single industry but a complex of different industries variously organized. With respect to shoes, where there are perhaps a thousand manufacturers, satisfactory points of control might be set up, back to which the consumers' coupons might filter for collection. In hosiery and apparel, however, the raw materials have alternative uses, and they proceed to the finished stages by widely differing routes. There is no narrow point in the market, through which the total supply regularly passes, where the administrators could withdraw the coupon currency and exercise the necessary controls. It is therefore not surprising that, in both Britain and Germany, the institution of rationing has been accompanied not only by a standardization of clothing types, but also by a reorganization and rationalization of the industry as a whole.

X. General Rationing

The rationing of specific commodities, or even blocks of commodities, is a consequence of particular material shortages. A general rationing system, however, depending upon the outlook of the analyst, is a necessary preliminary, substitute, or complement to fiscal policy. Specific rationing, in a market where maximum prices are fixed, merely ensures an equitable distribution of a scarce good; and to the extent that it limits total money expenditure in one direction; it exacerbates the problem of price control in others. General rationing, however, whatever its particular form, is designed so to limit spendable currency as to match the total value of consumers' goods in the markets.

This aim, theoretically, might be achieved by a fiscal policy sufficiently severe to withdraw funds from the system on a scale such that, at current prices, total spendable cash equalled the total value of consumers' goods. There are three major objections to this procedure. First, fiscal policy can control only the size of incomes, not the total supply of spendable cash. Therefore, those with substantial savings might successfully resist efforts to induce a reduction in their outlays for consumers' goods. Secondly, a fiscal policy of sufficient severity fully to

eliminate the inflationary gap seems, from recent world experience, politically unfeasible. Even in Germany, the consumers' position has been characterized by cash surpluses. Third, there remain, even in economies where conversion to the war effort has been carried to a maximum, a number of outlets for spending which do not require limitation. Perhaps the most important of these (assuming adequate limitation on new borrowing) is the liquidation of debt. To a considerable extent outlays on health, insurance, education, and entertainment fall in the same class. And, of course, there are no immediate reasons for discouraging the flow of income into cash hoards or War Bonds. It is, presumably, some combination of these factors which has restrained the Treasury's hand.

In the light of its day-to-day problems the ideal position for the Treasury would be one where consumers' expenditures were almost universally rationed and where the voluntary purchase of War Bonds was virtually the only satisfactory remaining outlet for surplus cash. The ideal position for the OPA would be one where the Treasury was limiting incomes to the value of available consumers' goods plus voluntary "harmless" expenditure.

Schemes for over-all rationing, in fact, emerge as a continuum, stretching from orthodox fiscal policy at one end of the scale to complete and direct allocations of particular resources and finished commodities, at the other.

Realistic controversy, on a middle ground, now centers on the relative advantages of rationing over-all expenditure, as opposed to rationing commodities by a point system. Both methods would permit wide areas of consumers' choice, within the limits of rationing in particular markets; but the point system, as usually presented, would involve a less thoroughgoing leveling of real income. All persons might, for example, spend an equal number of points on clothing; but those with larger incomes, spending more money along with their points, would get clothing of better quality. A point system of this type might well cause a diversion of resources into higher quality products, of greater profitability, at the expense of items of mass consumption. This is, however, a general characteristic of any system that permits unequal money incomes to express themselves in the market for consumption goods and, short of income rationing on an egalitarian basis, or total rationing of consumers' goods, it will tend to persist.

XI. Can the Freeze Hold?

The price freeze order was precipitated by a situation where a decreasing supply of consumers' goods, in the face of rising money in-

comes, caused a rapid increase in prices. In itself, the freeze order neither decreased money incomes nor increased the supply of consumers' goods. It was, essentially, the statement of a policy and of a purpose: "We shall distribute our resources and our consumers' goods, in the course of this war, within the framework of a clearly defined maximum price level." The steps necessary to implement this purpose—in rationing, subsidies, and in wage and fiscal policy—are being or must still be taken.

If no such complementary steps were taken, if the freeze operated without support, it would be violated in at least three ways. Without a reduction or neutralization of spendable income, large-scale black markets would spring up, and inflation would continue. Without formal rationing of scarce consumers' goods, informal, and probably inequitable schemes would emerge, with the retailer as administrator. Without an adequate wage policy, legitimate claims for subsidy, due to rising variable costs, would overwhelm the administrators.

The responsibility for holding the freeze thus rests in varied hands. The OPA has, in a sense, only one direct responsibility: it must be prepared to intervene promptly in unrationed markets, where shortages have lead to black market operations or to inequitable informal rationing. Less directly, but perhaps more important, it must, in consultation with the Treasury, achieve that combination of fiscal policy and rationing that will roughly equate the current value of consumers' goods with the funds consumers can or choose to place in the retail markets.[3] Finally, the OPA has a vested interest in preventing increases in money wages, especially in those instances where the increase in costs can not manifestly be borne by the manufacturer at current prices, or where the granting of a wage increase will tend to detonate similar demands elsewhere in the economy.

Of these tasks the most important is, of course, the adequate limitation of the funds consumers bring to the markets. And as the price administrators in each market deal with the chronic pressures against the price ceilings, each holding his own particular fort, they look back over their shoulders for aid. They look, overwhelmingly, to the Treasury. That is an experience not soon to be forgotten by academic men; and in consequence it is likely that future generations of economists, unlike their predecessors, will be brought up with a sharp sense of the common forces that affect the determination of an individual price and the price level as a whole.

There is a final major lesson to be learned from the relativelv success-

[3] The necessary equation might be defined roughly as follows: The value of consumers' goods at frozen prices must equal total current income plus withdrawals from savings minus taxes, voluntary savings, and "harmless" spending.

ful experience of Canada and Britain with this range of problems. It is that, with the coöperation of the public, and of the special affected groups within it, the desired price stabilization and pattern of distribution can be achieved; and that without such coöperation, the most prescient and complete legal administration might fail. In a very limited sense Canada was fortunate in that the ruling political party was regarded as sympathetic to business interests, and the price ceiling was administered, for the most part, by business men. There was, perhaps, less *prima facie* suspicion of official motives than was present initially in this country. In this setting, and under the Canadian constitution, a highly flexible system of controls has operated, capable of rapid alteration to meet changing circumstances. The magnitude of the American problem, the relatively sharp distinction between the executive and legislative branches, and the complexity of American political life make inevitable the greater difficulties that we face. It is, however, evident that aside from the formal correctness of the quantitative and qualitative judgments made by the various administrators charged with price control, rationing, and wage and fiscal policy, the success of the program as a whole will depend heavily on the good will and self-discipline of a public on which severe and unaccustomed restraints are being imposed.

Washington, D.C.

HOW TO RATION CONSUMERS' GOODS AND CONTROL THEIR PRICES

By W. ALLEN WALLIS

I

The growing scarcity of consumers' goods makes the problem of rationing them increasingly urgent. Sugar, typewriters, bicycles, automobiles, tires, and gasoline are already subject to direct administrative rationing. Although no widespread infringement of the sugar regulations is apparent, the experience with tires and gasoline, if it should become more general, would be tragic. Even with sugar the cost of administration is not to be blinked at in a country straining every nerve toward war production.

A fundamental difficulty with administrative rationing is that equal allotments do not result in equal treatment or equal sacrifice. This has been recognized for tires and gasoline, and varying quantities have been allowed different classes of consumers. But no administrative board can appraise the merits of claims for allotments above the minimum, nor can it control the disposition of the commodity once allotted. Perhaps it can determine that a gasoline user's work is important for defense and that no public conveyance is available; it cannot judge whether he could shift his residence, change jobs, ride with a neighbor. And most of its problems are far more complicated than this one. For success a rationing board requires a nearly unanimous feeling by the general public that rationing is necessary, that the board's methods are proper, and that its administration is competent, uniform and impartial.

In our economy goods have normally been apportioned through the price mechanism. The commodity goes to those who want it badly enough to pay the price, this being dependent upon need or taste for the commodity, upon the acceptability of substitutes, and especially upon incomes. The income element in determining the distribution of goods and services is always a source of social concern. This concern occasionally results in direct allocation of goods and services outside the price system, notably free education and medical facilities, and more often it leads to efforts to redistribute income, notably through progressive income, gift, and inheritance taxes.

In wartime the rôle of income in rationing through the price mechanism becomes crucial, whether the peacetime distribution of income

be regarded as admirable or abominable, for the wartime lowering of total consumption would push considerable fractions of the population below the subsistence level if peacetime differentials in living standards were maintained. In wartime, furthermore, the amount of money which consumers have and try to spend exceeds the amount of goods and services for sale. The excess, or "inflationary gap," causes a general rise in the level of prices, which may become a serious impediment to economic mobilization, by retarding the shift of resources, discouraging saving, encouraging hoarding of goods, and erratically shifting the burden of the war. To rely on the normal operation of the price system during the war thus would cause great inequities in consumption and serious obstruction of the war effort, and this in ways that would cumulate, weakening morale, encouraging further injustices in the distribution of goods, aggravating the inflationary movement.

Measures to restrict these disruptive tendencies so far adopted fall into two general categories: (1) over-all measures to reduce the inflationary gap, such as increased taxation, restriction of consumer credit, and government borrowing from consumers; and (2) specific controls, such as price ceilings and rationing coupons. The second kind of measure cannot control inflation; indeed, it was clearly recognized in the statement accompanying the Price Ceiling Order of April 28, 1942, that measures of the first category are essential for that. But the over-all measures are unwieldy, slow in their effects, and not sufficiently flexible to keep up with rapid and unforeseeable alterations in the magnitude of the inflationary gap—though they can doubtless be improved in detail, as for example by withholding income at its sources instead of waiting, as now, from two-and-a-half to twenty-three months to complete collection of income taxes. The specific controls embodied in the Price Ceiling Order and accompanying rationing devices, while they might alleviate gross inequalities if they functioned smoothly, actually cause great waste of whatever consumers' goods are available; in addition, the huge cost of administering them reduces the amount of consumers' and of war goods available. The waste of goods which they cause can be discussed best in relation to a constructive proposal.

The proposal set forth here is an amalgam of over-all measures and specific controls. It would effect the optimum allocation of scarce goods among consumers with infinitely less cost, friction and waste, and with far greater simplicity and flexibility than other methods. At the same time it would prevent inflation and facilitate economic mobilization.

II

Let us approach the general plan by steps. First, consider the problem of rationing meat. Beef yields various cuts in proportions which are

not easily altered. With consumer income rising and its usual outlets in durable goods closed, nearly everyone will try to buy the best cuts. Because of the price ceiling, the price cannot rise above its highest point in March, and at that price the demand will exceed the supply. Perhaps butchers will favor special customers, or perhaps a first-come, first-served policy will prevail. Either will cause considerable injustices and grumbling, all the more because those engaged in war work are likely to be too busy to shop early and wait in line, or are apt to have moved recently and so not to have established claims to a butcher's favor. As in the case of sugar, administrative rationing will become necessary. But it would be preposterous to assign to each person so many ounces per week of sirloin steak, so many of porterhouse, so many of top round, so many of bottom round, so many of rib roast, etc.

A far more intelligent policy is that of the English, who limit each person to a certain value of meat per week. Those who prefer quality to quantity can exercise their preference, as can those who prefer quantity to quality. Suppose the prices of different cuts are left to demand and supply, subject to the important restriction that each person's total demand is limited to, say, 75 cents per week. Then, if there is a general preference for quality, the prices of better cuts will rise enormously *and* the prices of poorer cuts will fall correspondingly. For, if everyone tried to spend most of his 75 cents on good cuts, their price would have to rise since their quantity is fixed; but no one would have much money left to offer for poor cuts and their prices would have to fall to dispose of them. As the differential increased a growing number of persons would be repelled by the rising price of good cuts and attracted by the falling price of inferior cuts. Finally, those who cared so much for quality that they were willing to restrict themselves to minute quantities of meat would get the good cuts; but as a penalty they would have released the great bulk of the meat to others. Those who decided to forego the quality cuts would be rewarded by more than proportionate shares of the quantity.

Suppose, on the other hand, a general preference for quantity and indifference to quality. Then everyone would try to buy the cheap cuts, consequently having little money left to spend on good cuts. The result would be to push the price of inferior cuts up and of superior cuts down, until the differential became very narrow; and meat would be divided almost equally on a poundage basis.

In either case, there would be real equality in the degree to which each person's needs and tastes were satisfied by the quantity and quality of his meat. Equality of sacrifice must take account of quantity and quality, and of the fact that the amount of sacrifice entailed by curtailing either is a subjective matter varying from individual to individual.

This is taken into account by restricting each person's total expenditure on meat, which in turn makes it possible to leave the prices of different cuts free to indicate the relative scarcity and desirability of the various cuts. The relative prices of different cuts might change freely, but no increase in the level of meat prices in general could occur, because the total amount of money spendable on meat would be fixed. If the amount of meat available were to increase or decrease, the allowable expenditure on meat would be increased or decreased by the same amount.

Now, there is no point in confining the merits of this system to meat. Much better results will be secured by extending it to all food, by limiting total weekly expenditures on food to, say, $3.00 per person. Those who greatly prefer meat to any other food then can expand their expenditures on meat beyond 75 cents. If they do, they will have less to spend on other foods, and those who give up meat in the face of the price rise caused by the meat-eaters will be rewarded by being able to buy more than their proportionate share of, perhaps, vegetables. The prospect of this greater amount of vegetables induces those who have no great craving for meat to leave the meat for the meat-lovers, and the rising price of meat reinforces this inducement.

Still more generally, the scheme should be extended to all consumption goods and services. Then those who are easily satisfied with little food—that is, with either small quantity or low quality—have an inducement to forego food and take their consumption in forms less desired by their more ravenous countrymen. There could be no inequality in total consumption: inequalities in consumption of different commodities would balance out for each individual, just as inequalities in quantity would be balanced by inequalities in the reverse direction in quality. The measurement of consumption would be in value terms, and value would reflect the relative scarcity of each good in combination with its relative desiredness by all consumers as a group. There could be no rise in the price *level,* of course, for the aggregate of the consumption allotments would equal the aggregate of the consumption goods and services available. Shifts in *relative* prices are highly desirable, for they give each consumer the data for balancing his wants against the wants of others, taking into account the relative scarcities of various goods; and they provide a powerful incentive for him to do the balancing in such a way that he consumes as little as possible of things that are scarcest or most desired by others.

Another important feature is that this system would not tie up any considerable amount of resources in its administration, and that it relies on control mechanisms which are already established and functioning in our economy, merely governing their action instead of replacing them entirely. To put the point in more general terms, the necessary wartime

control is achieved, not by putting an enormous staff to work participating directly in the millions of economic decisions and actions that occur daily, but by setting up a general economic environment in which each individual in every transaction has a simple measure (price) of how important each commodity is to the nation and at the same time has an almost compulsory incentive (the necessity of getting the most for his limited funds) to discover how he can best adjust to the national emergency—in whatever the degree of his patriotism.

Finally, it should be observed that shifts in relative prices can serve to shift the amounts of different commodities available. Sugar and coffee, for example, compete for whatever shipping space is allotted to such things. Should consumers, under their curtailed level of living, desire to increase the ratio of sugar to coffee this would be reflected by a much greater rise in the price of sugar than in the price of coffee (or perhaps a greater decrease in the price of coffee than in the price of sugar, if consumers were cutting down on both more than on other things). This change in relative prices would indicate that consumers would be better satisfied if some of the shipping space being used for coffee were transferred to sugar. Whether the transfer could actually be effected would depend upon a host of matters connected with importing, but at least the possibility of decreasing consumer sacrifice with no increase in shipping would be definitely known.

III

A uniform total-expenditure ration is, however, more drastic than is required in this country, at least in the immediate future. The degree to which it would equalize consumption exceeds by far what is necessitated by war conditions, and a sudden equalization of consumption would produce serious secondary shocks, both economic and psychological. Those who exert the greatest efforts during the war have, furthermore, a prior claim on current consumption (as well as on future consumption). Some flexibility in the maximum total consumption is desirable also to provide for extreme cases, whether arising from emergencies or peculiar needs and tastes. But administrative boards for these purposes would be dangerous: with the best of intentions and abilities equity would be impossible, and the mere suspicion of favoritism or of unevenness from time to time or place to place would be fatal. The amount of the total-expenditure ration should be fixed differently, however, for different ages, family compositions, etc., on a uniform basis, just as are personal exemptions for the income tax.

Flexibility in the total-expenditure ration can be introduced if, instead of prohibiting expenditures in excess of the total ration, a tax is levied on excess expenditures at a steeply progressive rate. A family of

four, for example, might be allowed a basic total expenditure ration of \$2,000 per year. (The figures used here, as in the foregoing examples of meat and food, are purely illustrative and do not reflect even guesses as to practical figures.) Any expenditures beyond \$2,000 would be subject to a 10 per cent tax, expenditures beyond \$2,500 to a tax of 15 per cent in addition to the 10 per cent, expenditures beyond \$3,000 to an additional 20 per cent tax, etc. Thus, it would be possible to consume more than the basic ration if current income were high, which by-and-large would be when individuals or their properties were engaged in war activities. As a matter of fact, as we shall see later, the present proposal itself would make it more true than it now is that high incomes correspond with intensive war work. But because of the tax, expansion of current consumption would entail a disproportionate and rapidly mounting contraction of post-war consumption; that is, the tax would cut heavily into savings which could be spent, free of the tax, after the war.

The problem of administering this plan for rationing consumer goods and controlling their prices reduces to the problem of administering the progressive consumption tax. To require individual accounting for consumption expenditures would not be feasible. It could be presumed that all income not saved is subject to the consumption tax.

The present income tax laws already provide for reports on income. No evidence of saving should be recognized, except government bonds. Thus, the government would minimize the problem of regulating all the diverse forms in which savings occur, and would be better able to control investment during the war. Altogether, the consumption tax might not increase appreciably the administrative burden of the Treasury—and certainly would not add to its burden in anything like the amount by which present and prospective Office of Price Administration operations would be eliminated.

Each individual, then, would file a federal income tax return in the usual way. To it would be appended a calculation of his consumption tax, consisting of four steps: (1) any adjustments necessary to bring his total net income figure into line with an income definition more appropriate to the consumption tax than are the income tax definitions; (2) deduction of the part of this income used for purchasing United States government bonds; (3) deduction of the basic expenditure ration, and of amounts used for any purposes specially exempted from the consumption tax; (4) computation of the tax on the balance obtained in the third step. Measures to speed collection, incidentally, would be as desirable in the case of the consumption tax as in the case of the income tax, and at least as feasible.

Perhaps the most difficult question in administration would concern liquidation of assets. In so far as assets, whether securities or such con-

sumers' goods as tires and toasters, were paid for by other consumers out of their current income, no harm would result, for no upward pressure on the price level would be exerted. It would be necessary to guard against liquidation by sale or mortgage to businesses, banks, or in general out of any funds not subject to the consumption tax. Without working out here all the details which would be necessary to implement the plan, it may be asserted confidently that a little legal, accounting, and administrative ingenuity can minimize the difficulties and the possibilities of evasion. In one respect at least, evasion of the consumption tax would be more difficult than evasion of the income tax: one's neighbors do not know either one's actual or reported income, but the only object of evading the consumption tax, increasing current consumption, would tend to make one conspicuous in a war community.

It is much easier to estimate the volume of production of consumers' goods and services, all that would be required for determining the basic or tax-free expenditure ration, than it is to estimate the inflationary gap. The only adjustment would be to allow for spending above the basic ration in the face of the tax. This could not be of great importance, because the number of people having sufficient incomes to spend much above the basic ration would be very small if the tax were sufficiently progressive, and most of them would be deterred by the tax.

The consumption levy is not a tax in the usual sense. It is a transitionary device for reducing and equalizing consumption to the degree that may become necessary during the war. The income tax, because it affects consumption only indirectly, is not sufficiently flexible to do this efficiently, especially without impairing the power of differential earnings to transfer resources into war activities. The consumption tax, however, cannot be relied upon for revenue—indeed, the better it fulfills its function, the less tax revenue it yields—so it would not diminish the necessity of income taxation. Sales of government bonds induced by the consumption tax, together with the income tax, would guarantee adequate government finances during the war. But if the bond sales were to carry the principal burden, the structure of the government debt might create post-war problems of income distribution. The inequalities of consumption that were suppressed during the war would cumulate, to be released with exaggerated force after the war. If excessive concentration of government bond holdings is limited by proper use of the income tax, the funds saved to avoid the consumption tax could constitute a powerful aid to post-war economic adjustment.

IV

Having arrived at a basic total-expenditure ration and steeply progressive consumption taxes, let us for a moment forget the route by which we traveled and survey an alternative path which sets out to levy

a progressive sales tax—that is, to charge higher prices to high-level consumers. The scheme set forth above accomplishes this neatly.

Consider, for example, three purchasers of the three tires remaining on a car that has worn through its other two. Let us suppose that A, B, and C are each entitled to a basic total-expenditure ration of $2,000 per year, and that supply and demand, as controlled by total-expenditure rationing, have set a valuation of $25 on each tire. A, B, and C each purchases one to round out his own set of three remaining tires.

Before considering the situation described, let us digress to note that this situation implies that the seller has decided the things he can buy with $75, plus what he can get for his car, are more desirable to him than the services of the car, especially in view of the high costs of operating it. The reason he can get so much money for his tires and car and so many other things with the money is that people like A, B, and C, who need cars—or think they need cars, and what man can distinguish between "real" and "illusory" needs?—are spending so much on car operation that they have been forced by the ceiling on total expenditures to withdraw from the markets for other things, thus letting down the prices of other things and attracting our tire-seller into the vacuum they have left.

Returning to the purchasers: The apparent price of a tire to each buyer is the $25 the seller receives from each. If A's total expenditures are under $2,000, $25 is the real price to him. But to B, who is spending between $2,000 and $2,500, the real price is raised by the tax he must pay, say 10 per cent, to $27.50. And to C, spending $3,100, the price is raised by the tax, say (using the arbitrary figures set down earlier) 10 per cent + 15 per cent + 20 per cent = 45 per cent, to $36.25. The reason D, whose total expenditures are a trifle over $10,000, is not in the market for a tire is that it would cost him, with tax, $237.50 (projecting the figures used earlier, which rise by 5 per cent for each $500 of expenditure).

The reason for charging higher prices to higher income groups is, of course, that they require a greater stimulus to curtail consumption, since they have the possibility of simply reducing saving. It is to be recalled that if they refrain from consuming now, they can get full value in goods after the war when consumption rationing is halted, and this possibility reinforces the stimulus to minimize current consumption.

There would be little danger from purchases by those for whom the tax is low in behalf of those for whom it is high. Such a transaction would be an effective evasion only if it were based on a promise by the high-level consumer to repay after removal of the consumption tax. The actual purchaser would have to forego current consumption equal to the price of the commodity to him, and in return he would receive

an illegal credit instrument of indefinite maturity. People who can rely on one another to fulfill obligations of that nature are likely to be of more or less similar social and economic status, hence affected approximately alike by the tax; and the integrity required will not often accompany sly circumvention of emergency war measures that are obviously uniform and objective in their incidence. But the most effective obstacle to arbitrage is that the person who extended credit would have to do so out of his own total-expenditure ration and income; and, if his expenditures were low enough to make his tax low, he could not extend much credit—because he would have to cut into his own consumption, or else he would incur taxes curtailing his income and hence his power to extend credit.

V

In evaluating a proposal of this kind it is essential to consider not only its primary effects but its secondary repercussions. In considering these, however, it is important to distinguish between consequences that are fundamental characteristics of the war situation and its attendant hardships and consequences not inherent in the war situation but only in the particular plan of meeting it. The object of any plan is, of course, to smooth the course and spread the impact of consequences of the first kind, with a minimum of undesirable consequences of the second kind.

As an extreme example of the secondary repercussions of the plan, imagine its effects on a luxurious summer hotel so located as to be of little potential use to the military forces even as a convalescent home. Perhaps it had been patronized exclusively by persons with incomes in excess of $10,000 per year. If its nominal rates were $20 per day, extrapolation of the illustrative progressive consumption tax figures used before would raise the minimum effective price to the patrons to $190 per day. The management would be faced with the necessity of lowering its rates to serve lower income groups. To curtail costs it would have to reduce the size and quality of its staff and of the articles furnished. The staff, in order to continue receiving incomes, would be forced to look for other jobs, and the place to look would be in war work. Indeed, the management might well decide to liquidate its mobile assets, selling plumbing, hardware, rugs, vacuum cleaners, dishes, tableware, linen, furniture, and its whole inventory of things no longer being produced but badly needed because of population shifts under the war program.

In effect the hotel staff would have received notice that its former services were not contributing as much to a nation at war as they had to a nation at peace. It would have a full range of accurate information as to how it best could contribute to the war: if its assets were mobile (the cost of removal and shipment would indicate how mobile they were from a national point of view) and were scarce and urgently

needed elsewhere (the prices being offered by consumers out of their total-expenditure rations would show how badly they were wanted in relation to their scarcity), it would have a strong incentive to dismantle; but if the losses entailed in this were greater than those of continuing to operate at low rates it would have evidence that it services are more useful (less useless!) as it is. The owners and employees would find themselves in unfortunate circumstances, like those already confronting automobile dealers and operators of tourist cabins; but their burden would be an unavoidable result of the fact that their services did not contribute materially to the war effort, and it would be alleviated by the opportunity, through the freedom of the prices of their assets, to recover some of their losses.

This example is perhaps an extreme one. It has been chosen deliberately to show the worst possible secondary repercussions and indicate that even in such circumstances the proposed plan may alleviate an unavoidable hardship and expedite adjustment to the requirements of the war economy: the hotel management being under compulsion (financial) to apply all its ingenuity to discovering uses for its assets.

VI

The program should be put into operation without delay. If it is put into effect now, it will not have to set the initial total-expenditure ration extremely low and the progressive features need not be severe, because the volume of available consumers' goods and services has not yet declined markedly. As the decline proceeds, people will be able to organize orderly retreats from their peacetime standards of living, and shifts in relative prices will be sufficiently gradual to facilitate readjustment of the economy to the new structure of demands. The longer the economic changes due to the war are forced to operate under a system of fixed individual prices, the greater will be the maladjustments; and the larger will be the amount of direct governmental participation in the detailed decisions of individuals that will be necessary for the functioning of the economy under any scheme.

It may seem that, even with the plan in effect, one or two items might become so extremely scarce that even if divided equally there would be barely enough to go around, and that administrative rationing would therefore become necessary for such items. Despite the plausibility of this reasoning, it is fundamentally fallacious. Such extreme scarcity cannot exist apart from a general scarcity, because goods are substitutable both in consumption and production. On the consumption side, there is no single good nor any small group of goods that cannot be replaced more or less satisfactorily by other goods. On the production

side, a desired result can be achieved in a variety of ways, and any particular resource has innumerable potential uses.

All these possibilities of substitution quickly convert what would otherwise be an acute specific shortage into a mild general shortage. A shortage of tires, for example, becomes a lack of truck-hauled vegetables, and this leads to greater demands for rail-hauled vegetables, thereby slightly increasing the scarcity of refrigerator cars; it becomes a lack of access to factories, which leads to housing construction near the factories, hence increases the scarcity of building materials; it becomes a lack of urban transportation, which leads to increased use of trolleys and subways, hence to increased demands on electric generators, and so to scarcity of illumination. Every specific scarcity becomes an indistinguishable part of the general scarcity. As the general scarcity accumulates, total-expenditure rationing must become increasingly strict. Lower basic rations and more steeply progressive consumption taxes must come into force, for this is the best means of minimizing the hardships from the general scarcity and of distributing them equally.

Undoubtedly a large number of exemptions from the total-expenditure ration will be proposed. Very few if any of these will bear analysis, though many seem acceptable at first. To establish any exception would be a dangerous precedent. To exempt medical expenses, for example, would benefit only the upper-income groups, since in general the lower-income brackets do not have the money to try to spend even in emergency, but must rely on social facilities. Those whose expenditures are high enough to subject them to a high consumption tax would be those whose standard of living was enough above the general average for them to make the unpleasant adjustments that the vast majority of the population must make even in peace when medical expenses are incurred; otherwise, they could resort to facilities available to families unable to assume the full cost of medical care. Exempting one item would greatly encourage its utilization by the upper-income groups. Medical facilities in wartime are extremely overburdened and their use has to be curtailed below an "adequate" level simply because there is not an adequate amount in existence.

A general class of exceptions probably will be put forward with the object of "directing consumption to those items which do not use up war materials." The fact that this can be accomplished most effectively by fixing the general price level in such a way as to leave *relative* prices free to reflect scarcities and wants is, however, one of the most cogent arguments for the proposed plan. Furthermore, there is nothing to be gained by encouraging the consumption of such goods except in so far as they can replace goods using war resources; so the better able such

goods are to satisfy consumer needs the smaller should be the consumer's remaining claim on other goods.

There is perhaps a case for exempting payments on debts contracted prior to adoption of the plan. Insurance payments pose a problem, but not an insuperable one. In so far as they represent pure insurance they are transfers from one consumer to another, hence the premiums should be exempt but the benefits taxed if the beneficiary spends them; in so far as they represent service fees they are consumption, so should be subject to the tax; and in so far as they represent savings they should come under government control. A possible device, which could be extended also to other savings institutions, would be for the insurance companies to buy government bonds to which were attached coupons that could be distributed to policy holders for use as evidence of savings when computing the consumption tax.

On the income side of the picture, it would be desirable but impractical to include the income-value of durable goods. Perhaps in the case of houses, the rental value of owned homes might feasibly be added to income and expenditure. In so far as the amount of other durable goods owned tends to be correlated with income, the progressive features of the tax schedule would compensate for them.

VII

A system of total-expenditure rationing, coupled with a steeply progressive tax on all expenditures in excess of the basic ration, would be enormously superior to the devices now being inaugurated, because it would (1) effectively prevent inflation; (2) achieve the fairest and least wasteful distribution of consumers' goods; (3) be administratively simple and flexible; (4) avoid the disruptive consequences of (a) suspicion of favoritism or incompetence, actual or illusory, by administrative boards, (b) widespread disregard of law, (c) extensive policing investigations and control of private affairs, (d) elaborate red-tape, delay, and frustration in economic matters, (e) concentration of individual efforts on persuading or educating administrators instead of on solving difficulties, and (f) extensive diversion of resources to nonproductive, regulatory functions.

The proposed tax is essentially a progressive sales tax. As such, it bridges the gulf between the advocates of a sales tax, who rightly emphasize the desirability of discouraging consumption by direct taxation and the difficulties of relying exclusively on income taxation; and the advocates of exclusive reliance on income taxes, who rightly emphasize the desirability of progression and the regressive incidence of uniform sales taxation.

Stanford University

GENERAL EXPENDITURE RATIONING WITH PARTICULAR REFERENCE TO THE KALECKI PLAN

By Ralph E. Holben

Introduction

Rationing is a logical concomitant of any policy designed to control retail prices, since it is the only way in which the discrepancy between mounting consumers' demand and limited supply can effectively and equitably be handled. To fix prices at the retail level without a general plan for rationing would result in an informal sort of rationing by the seller wherein any prejudice or preference he may have could exert an undesirable influence; *ipso facto* rationing is a prerequisite to any program which would distribute limited supplies equitably to the consuming public.

Since the fundamental theory of rationing is to equate demand and supply and thereby perform (in a limited sense) the function of the price mechanism, any plan of rationing must seek to regulate the flow of rationed commodities from the manufacturer to the retailer as well as the ultimate sale to the consumer. Once it is decided some form of rationing is necessary, *pari passu* it follows that a complete program coördinating output and consumption must be adopted. Specific rationing, such as point rationing, if effectively administered, can equate demand and supply and distribute limited supplies equitably among the consuming public. Specific rationing has the virtue of being able to meet particular problems of economic maladjustment as they arise. General expenditure rationing, while it will bring about a state of stability in the general price level, will create innumerable problems of disequilibrium in the case of particular commodities, the impact of which would tend to disrupt the entire economy for some period of time.

As this discussion is developed, it will be shown that, though Mr. Kalecki fully appreciates the theoretical necessity of a program of rationing, his plan for carrying out such a program is both theoretically invalid and practically quite unworkable.

This paper will demonstrate that the general principle of expenditure rationing is quite incompatible with the present program for price control in the United States.

Kalecki's General Approach to Rationing

In essence, Mr. Kalecki's plan amounts to a general limitation of the amount of funds which may be expended on commodities purchased in retail shops.[1] He thereby hopes to curtail total consumption for such commodities so that demand for them will not exceed supply; any inflationary tendency which might exist in such retail prices should, thereby, disappear. It is important to realize, however, that the tendency for other prices to increase will not be diminished; in fact, it is most likely that many other prices will receive a tremendous inflationary impetus, because of a shift in the expenditure patterns of the higher income groups. Funds formerly spent in retail shops will flow into other channels for the purchase of real estate, for travel, or for services. Kalecki fails to recommend any plan for the specific rationing of these items, nor does he seem to realize that the rationing problem in their case will be multiplied as a result of his plan.

Mr. Kalecki rejects a plan for specific rationing on the grounds that such a plan would have to assume enormous proportions, would result in considerable inconvenience, and would be difficult to control. The recent experience of Germany and England does not prove this to be the case; at least, one might say that such problems have not proved to be insuperable, since both of these countries have been engaged in specific rationing, and no evidence has appeared to indicate a serious breakdown in their respective programs. Kalecki also suggests that specific rationing would result in the transfer of coupons from the poor to the rich so that a surplus would be distributed among the rich in a "haphazard and disorderly fashion." There may be some truth in this criticism, but it hardly represents a serious attack upon the coupon method of rationing. Since it is desirable to leave a certain element of free choice to the consumer in the distribution of his income so that he can maximize his satisfactions, there is no apparent reason why the poor should have to consume the total value of their weekly ration. In fact, many of the poor cannot afford to do so, for if they prefer to obtain a greater marginal unit of satisfaction from the sale of one of these coupons so that they can thereby purchase some other article, why should they not be able to do this? It is of course true that the random sale of such coupons among those people who can afford to consume a surplus will not afford purchase opportunities to all buyers. Since the equilibrium between demand and supply planned in accordance with the rationing scheme would not be affected, there does not seem to be any reason why the sale of unused coupons should

[1] M. Kalecki, *General Rationing*, Bull., Inst. of Stat. (Oxford, England), Vol. 3, no. 1 (Jan. 11, 1941).

not take place. It would therefore be wise for the government to buy all of such a surplus of coupons at a fixed price and resell them with a sizable margin of profit to all buyers who are able to purchase them. The resale could be based on a plan wherein a buyer would have to purchase a special permit, which would allow him a just percentage of the available surplus. Thus a special rationing plan of surplus coupons could be superimposed on the basic rationing plan. The chief advantages of government distribution of such surplus coupons lie in the revenue it will provide and in the greater equity it will impart to the distribution system.[2]

Mr. Kalecki proposes to substitute a "general rationing scheme" for specific rationing because he believes that such a plan will do away with the problem of the transfer of unused coupons and simplify administrative procedure. His plan calls for the issuance of general coupons encompassing the total expenditure allowed to an individual in retail shops. Such a general coupon book would replace the numerous specific coupon books required by specific rationing. Thus, by assumption, this limitation of expenditures will increase the desirability of consumers to purchase rationed commodities, as contrasted to any other possible use of their income, to such an extent that very few if any individuals in any income group will desire to sell a surplus of their own coupons. He proposes to fix this expenditure at 25 shillings a week for an adult and 14 shillings for a child, with a few exemptions such as services, books, and medicines. Therefore, Kalecki's scheme calls for a tremendous consumption sacrifice from the higher income categories. In addition, Kalecki proposes to prevent the transfer of coupons under this scheme by the following provision: "Apart from the absolute maximum of expenditure, a maximum percentage of income to be spent in retail shops is fixed at a level equal approximately to the upper limit of the actual percentage spent in shops by the poorer population, say 80 per cent. Coupons must then be issued for the amount corresponding to the lower of these two maxima."

The "Raison d'Etre" of the Plan

A plan of general expenditure rationing theoretically seems to possess unique advantages not characteristic of specific rationing, those of simplicity and comprehensiveness. In one fell stroke, the institution of an expenditure rationing plan would stabilize prices, provided that the scheme were effectively administered and that it could close the "gap" for any given period of time. The plan has the advantage of

[2] Equity implies in this sense equal opportunity for all buyers to share in the purchase of surplus coupons.

increasing net saving to the degree to which it limits expenditures on consumption goods; it approaches the problem directly by attacking inflation at its source through a reduction in the amount of money income available for consumption;[3] this is a virtue not possessed by Keynes's deferred payment plan whereby net saving would fail to increase to the degree to which increases in forced saving were offset by dissaving. The general expenditure rationing scheme also avoids the weakness of allowing high income earners to escape sharing in the general contraction of the consumption standard of living by means of capital consumption; this weakness must of course be associated with any plan of "deferred pay."

But the general expenditure rationing plan, though it would close the inflationary gap, has certain associated disadvantages which may well outweigh its primary attribute. The following criticisms pertain, to an equal or lesser degree, to the theory of general expenditure rationing, but they are particularly concerned with the specific proposal of Mr. Kalecki.

Objections

Let us now consider in some detail the possible objections that might be raised.

The first and probably the most serious objection to the Kalecki plan lies in its failure to cope with the problem of limiting consumers' demand to a planned allotment of supplies. A simple example will reveal this failing. If we assume that the total output of a country to be 100 units, 60 units of which will be devoted to the production of consumers' goods, there arises the problem of how to divide this 60 per cent of productive power in the production of alternative types of consumers' goods. Before the initiation of the limited expenditures plan, the plants of the manufacturers of commodities, later to be rationed, will be geared to produce in accordance with the particular demand functions (conditions) prevailing for their respective commodities. After the adoption of the Kalecki plan wherein a maximum level of expenditure in retail shops was fixed by decree, a violent change in the demand functions for the various commodities would immediately ensue as a consequence of the income use and substitution effects arising from this expenditure limitation; not only will the elasticity of the "particular" demand curves for these commodities change, but—more important—the total volume of demand for most of them will have undergone a drastic revision.[4]

[3] Savings, by definition, will be considered to be money not spent on consumption.

[4] These changes may be expressed by the following equation: Before the limitation of expenditures, $10Da + 20Db + 15Dc + \dots + NDn = X$. Da, Db, etc., = Total demand for

For example, after the limitation of expenditures has been instituted, higher income group consumers will purchase much smaller amounts of consumers' durable goods, of which they already have considerable supplies, and concentrate their purchases on perishable products. The degree to which this shift will occur would of course be beyond the powers of anticipation of any business man; not only would this be true, but even were he able accurately to predict his future demand, time would forbid his making adequate adjustments to meet the situation. The result of this situation will be that producers and retailers of consumers' durables will have excessive supplies that cannot be sold at cost price, while dealers in perishable necessities will be unable to supply the new demand. Consequently, not only does a severe price problem arise, but an enormous amount of waste is entailed.

The end result of this process will be that not only will existing supplies in the form of accumulated retailers' inventories be maladjusted to the new direction of consumers' demand, but existing productive facilities will not be adapted to the new pattern of demand. The full significance of the unfortunate economic consequences of this plan are now apparent. Not only does a new plant conversion problem result, but existing supplies are not equated to the new demand pattern. Thus a new problem in the rearrangement of price ceilings will arise. Yet, this is not the final consequence; for, as industry tries to readjust its plan to what it anticipates to be the new pattern of demand, demand functions may again change due to the unpredictable effect of this unique situation (the limitation of aggregate expenditure) upon the consumers' desires. Thus one must conclude that not only will an equilibrium of demand and supply be nonexistent after the instigation of such a plan, but the reëstablishment of such an equilibrium will be difficult over an extended period of time.

Second, although the general level of prices could be stabilized under general expenditure rationing, the preëxisting price structure would undergo a tremendous alteration under the influence of changing demand functions; the preëxisting equilibrium relationship of individual prices would be completely upset. Such a disturbance of the integration of the price structure would render impossible the maintenance of the general freeze of retail prices as of March, 1942. The present policy of the Office of Price Administration concerning a general freeze of retail prices, if not rendered superfluous by such a plan,

---

specific commodities, NDn = total demand for all other commodities, X = total demand for all commodities. After limitation of expenditures, the demand equation might become, for example, $15Da + 6Db + 21Dc + \dots + NDn = X$.

would at least have to be postponed until such a time as a new equilibrium in the relationship of individual prices had again been attained. This criticism, of course, is directed toward the practicality of using such a plan in this country at the present time in view of prevalent policy rather than toward the value of the plan in itself. The extension of specific rationing in accordance with the development of shortages for specific commodities is the logical concomitant to the present policy of stabilizing the general price level.

To be more specific on this point, after the institution of general expenditure rationing, the prices of most individual commodities would tend to move above or below that equilibrium level which they had attained prior to the institution of the plan. Therefore, the attempt to use general expenditure rationing in conjunction with the present price freeze would mean that those prices which should rise in accordance with an increase in demand could not rise; it would be impossible, therefore, for output automatically to be adjusted to changes in demand via the medium of price changes. Thus, it would be impossible to retain the price ceiling at the same time that one introduced expenditure rationing without completely destroying the allocative function of the price mechanism. The disruption to output and the smooth functioning of the productive mechanism would, therefore, indicate general rationing to be quite incompatible now with the general freeze.

The third objection relates to the stupidity of utilizing such a scheme as Kalecki suggests at the present time in the United States. While rationing may soon become a necessity in the case of many commodities, there are numerous commodities sold at retail, the existing supplies of which are plentiful and the future supplies of which should not be greatly reduced, which need not be rationed. The introduction of Kalecki's maximum expenditure plan might mean that many of these commodities could not be sold at cost price, because of the substitution and income effects arising from such a limitation. This would give rise to an unnecessary burden to retail dealers.[5]

An unfortunate repercussion of this situation would be its disastrous effect upon civilian morale, when consumers realize that there are numerous commodities available for consumption which cannot be consumed because of the limitation of total expenditure. A similar effect would manifest itself among producers of commodities for civilian consumption and retailers who endure unnecessary costs of conversion and excessive supply.

Fourth, the extreme limitation imposed under Mr. Kalecki's plan

[5] The latest available statistics reveal a significant increase in retail inventory accumulation during the past year. See F. C. Murphy and L. J. Paradiso, "Business Inventories in the War Period," *Survey of Current Bus.*, June, 1942, pp. 6-26. Note especially Table 2, p. 7.

on the expenditure in retail stores would drastically reduce the standard of living of higher income earners to such an extent as seriously to impair their morale and productive efficiency. Perhaps the higher income earners should be classified as those who earn an income in excess of $2,000 a year since less than 35 per cent of the population is included in this classification. For purposes of illustration, however, I will take that category of persons whose income is in excess of $5,000 and who comprise but 5 per cent of all families and individuals. The aggregate consumption expenditure of this group amounts to $12,295,000,000, and there are 2,153,000 individuals in this group so that the average annual expenditure on the main categories of consumption for these individuals amounts to approximately $5,711.[6] This amounts to an average expenditure of $110 a week. After taking account of expenditures which are not made in retail stores, it would still be true that approximately $60 a week is spent in retail stores by the average individual in this group. Mr. Kalecki would limit his expenditure to 25 shillings or about $5.00. It should now be plain why a limitation even remotely approximating that which Kalecki suggested for England would result in a drastic reduction of the standard of living of the higher income category in the United States. Even after making allowances for a generally higher standard of living in the United States and a greater burden of taxation in England, Kalecki's scheme would call for a limitation of expenditures in the United States to about $9.00 a week. This amounts to an 85 per cent reduction in consumption to the higher income classes.

Therefore, Kalecki's scheme results in such a drastic reduction of consumption income to the higher income groups and stabilizes the level of consumable income at such a low level as to raise grave suspicion that individual productive efficiency would be reduced. The wiping out of income differentials in this fashion has never been successfully utilized by any modern economy in peacetime or wartime.

Conclusion

My attack on Kalecki's plan for general rationing can be summarized as follows: (1) because it would offer no means for industry to foresee necessary adjustments in plant capacity, since it would create a tremendous conversion problem, it is, therefore, economically inefficient; (2) it is incompatible with the policy of a "general price freeze" because it would upset price equilibrium and destroy the allocative function of the price mechanism; (3) it is especially ill

[6] *Revenue Revision of 1942,* Hearings Before the Committee on Ways and Means, House of Representatives. (Rev.) Vol. I, Mar., 1942, Table 3, p. 364; Table 8b, p. 373.

adapted to the present stage of war industrial development in the United States, because it would result in the creation of large supplies of nonconsumable retail goods and thus would be destructive of morale; (4) Kalecki's plan results in such a severe leveling of income differentials, in so far as a very considerable restriction in the use of income is involved, that the productive efficiency of higher paid workers might be severely reduced.

If, instead of establishing an absolute level of expenditure for all individuals, different individuals were allowed varying expenditure rations in accordance with the level of their income (people with larger incomes being allowed a smaller percentage of their income for consumption than those with relatively small incomes), then my fourth objection to the Kalecki plan would be eliminated. The purpose of expenditure rationing could as adequately be accomplished by allowing differentials in the absolute amounts of income permitted for expenditure as by fixing one absolute level of expenditure. The other objections, however, would still apply to this variation on the Kalecki plan.

Specific Rationing

The general expansion in the use of specific rationing in conjunction with more intensive taxation and public saving appears to be the most satisfactory method of controlling inflation in this country at the present time. The extensive application of specific rationing to commodities (especially necessities) where shortages exist will accomplish the following objectives:

1. Assure the equitable distribution of limited supplies to the consuming public;
2. Relieve pressures endangering the maintenance of price ceilings as such pressures arise; and
3. Encourage voluntary saving as the possible uses of surplus money income become increasingly limited.

Specific rationing involves none of the accompanying defects such as have been attributed to general expenditures rationing because:

1. Through specific rationing it is possible to plan for the future the amount of any particular commodity which the civilian population will be allowed to consume. Since producers will know in advance how much of any particular commodity they may produce for civilian consumption, and since they also know that under wartime conditions there rarely will be any difficulty in selling the total supply of such goods,[7] the problem of adjusting output to unpre-

[7] The implicit assumption is made that money income held for purposes of consumption exceeds the value of available consumers' goods at current prices.

dictable demand conditions, a phenomenon typical of general expenditures rationing, would not exist. Thus specific rationing, by allowing producers and distributors to have precise knowledge concerning output functions and demand conditions, will result in a maximum of efficiency in the conversion of plant facilities to the demands of a war economy.

2. Specific rationing would in no way interfere with the maintenance of a general price ceiling; in reality, specific rationing would be an excellent instrument for the relief of the pressure of demand on particular price ceilings when such pressure becomes intense.

3. Specific rationing would avoid the paradox of "scarcity amidst plenty" which has been pointed out as a fundamental defect of general expenditures rationing. Under specific rationing there would be little danger that supplies of consumable goods would accumulate in stores as unconsumable stocks, since it is possible to plan to ration the total of existing stocks equitably to the consuming public. Specific rationing also implies that goods will be rationed only when shortages create a real need; it can then assure consumers that no one need worry about getting a fair share of existing supplies.

4. Finally, specific rationing allows higher income earners to enjoy the advantages of their higher income through the unlimited purchase of those commodities (especially luxury articles) which need not be rationed. Thus, specific rationing avoids the objection peculiar to Kalecki's conception of general expenditure rationing, that of leveling the real standard of living of all income earners with respect to a large proportion of current consumption.

The object of general expenditure rationing might be attained by a program of taxation and compulsory saving sufficiently extensive to close the gap. Unfortunately both of these measures have an inherent weakness previously alluded to, that is, the possibility of dissaving by higher income earners. Widespread dissaving would not only weaken the fiscal measures designed to close the gap, but would also result in an inequitable distribution of limited supplies by allowing high income earners to maintain their real consumption standard of living through capital consumption. While general expenditure rationing would avoid this difficulty, the already discussed weaknesses inherent in the plan render it unacceptable. Finally, even granted that a program of heavy taxation and compulsory saving could close the gap and would be politically acceptable, both very dubious assumptions, such a severe limitation on the use of money income would be subject to the *first three major objections* previously directed at the general expenditure rationing scheme.

It is, therefore, necessary today to follow the best possible course of action in view of prevailing economic and social conditions. This course of action calls for the extensive use of specific rationing to rectify severe maladjustments of demand and supply as they arise in the case of particular commodities. Whereas it is desirable to reduce the size of the inflationary gap by means of fiscal measures to relieve the pressure on price ceilings from the side of demand, it is probably neither possible politically nor desirable economically to close the gap during the present transition stage in the development of a full-fledged war economy.

The most serious objection that may be raised to specific rationing accompanied by a fiscal program that would narrow the gap but fail to close it would be the inflationary pressure exerted on unrationed commodity prices. Such demand bulges, however, would endanger the ceiling prices of only the less strategic commodities and would not offer a serious threat to the stability of the general price level. It is also likely that such surplus money income available for consumption would be saved rather than be spent on unrationed goods that have a low marginal utility value to the consumer.

It should not necessarily be the object of government price policy during wartime rigidly to maintain a given price level. Moderate increases in certain prices under the pressure of demand or rising costs could be sustained by the public without serious effects. One of the primary objects of government control of prices during wartime is to prevent a serious reduction in the standard of living of those income receivers whose money income will not increase in proportion to a general inflationary increase of prices. The general application of specific rationing to all the vital constituents of the cost of living index should assure the stability of the prices of such commodities and assure the basic living standard for the consuming public. The other primary object of government price control is to prevent precipitous price increases from causing a misdirection in the flow of investment funds which might endanger the maximization of wartime productive efficiency. In wartime it is essential that new investment be confined to those industries that are essential to the war effort. Such moderate price increases as have been alluded to would be insufficient, if they occurred at all, to effect any misdirection of investment, providing the government has adequate powers to control the distribution of raw materials through quota arrangements and priority controls.

There is no utopian solution to the inflation problem created by modern warfare. The most desirable policy for handling this problem must be measured not only by the degree to which it stabilizes the price level, but also by the degree to which it facilitates a rapid and

effective conversion of American industry to a full-fledged wartime basis. Thus, the inflation problem created by modern war is not only a problem of preventing a precipitous rise in the general price level, but also a problem of adjusting the price mechanism to the demands of wartime economic conditions in such a fashion that economic efficiency is maximized both in the production of war goods and in production and utilization of the residual available for civilian consumption.

In so far as rationing can contribute to a solution of the inflation problem, so defined, our government should continue in the intelligent application of *specific rationing* rather than make a radical departure from its present anti-inflation program by adopting a plan of general expenditures rationing.

Washington, D.C.

SUBSIDIES AND PRICE CONTROL

By Raymond F. Mikesell and C. Edward Galbreath

The establishment of comprehensive programs of price control in the warring nations of the world has resulted in the widespread use of subsidies. Subsidies are being employed not simply for holding down the prices of a few cost-of-living commodities for the benefit of the lower income classes, but as an instrument of primary significance in the modern technique of price control.

The earlier sections of this article will be devoted to a discussion of the use of subsidies as a fundamental technique of price control both in this country and abroad. The final section will be concerned with the economic justification of subsidies and an analysis of the effects of subsidy payments on inflationary pressure.

British Experience

Great Britain, although not having an over-all price ceiling, has substantially abandoned the practice of adjusting prices upward with increases in costs and has adopted the policy of insulating the prices of cost-of-living commodities, particularly food and clothing, from rising costs by direct government subsidy payments.[1] The British government has been subsidizing the retail prices of basic food products since December 1939, when the policy was instituted in an effort to retard the increase in the cost of living. In January 1940, the Chancellor of the Exchequer stated, "Our policy . . . is to make public money available . . . to hold retail prices of staple foods, or at any rate, to impose delay and check the abruptness of any rise."[2] By limiting inflationary price rises, it was hoped also to facilitate wage stabilization and to sustain public morale.

This program, however, was not extensive enough to hold down the cost of living. During 1940, living costs continued to increase and by April 1941, were almost 28 per cent above the pre-war level; the food component advanced 24 per cent.[3] At that time the Chancellor

announced the government's determination "to prevent any further rise of the cost-of-living index number, apart from minor seasonal changes, above the present range of 125-130 in terms of the pre-war level."[4] An important aspect of this program to stabilize living costs is the payment of subsidies not only for foods but also for transport, wool, hides, and coal.

The British have adopted several methods of subsidizing cost-of-living commodities.[5] One procedure is to rebate customs duties, as in the case of tea. A second method consists in direct subsidy payments to producers, as in the case of the subsidy for bread and the milk subsidy early in 1940. A third technique is the purchase of a commodity and its resale at a loss. Wheat, for example, is purchased by the Ministry of Food and sold to millers at a price sufficiently below the purchase price to keep the wholesale flour price from rising. A fourth technique is illustrated by the subsidy for cheese in the earlier months of the war. The Ministry of Food at that time did not fix prices but simply purchased certain quantities of imported cheese and sold them at lower prices to keep down domestic prices. As the subsidy had to be paid on only a small part of the supply, its cost was low. As a fifth method of subsidizing cost-of-living commodities, the British have been paying part of the increased cost involved in coastwise transport of food.

By extensive use of subsidies and other price-control devices, the cost-of-living stabilization program has met with considerable success. This is evident in the report of the Chancellor of the Exchequer that the cost-of-living index number remained virtually stationary between April 1941 and April 1942.[6] Although the total cost of the subsidy program has not been published, that for food alone is running at an annual rate of £127 million.[7]

Canadian Experience

The Canadian government and the Wartime Prices and Trade Board became convinced, after a thorough consideration of all the difficulties and conditions involved and after a reëxamination of the Canadian experience with price control, that it was necessary to hold the over-all price ceiling without a break. To hold prices firmly and pay subsidies when necessary were believed to be much less costly and more equitable than to permit upward adjustments of prices as costs rise. In a speech

in the House of Commons, J. L. Ilsley, Minister of Finance, contended that "Each increase in prices permitted by means of a flexible ceiling would be bound to lead directly to other movements. . . . This sort of process would gather momentum like a snowball rolling down hill."[8] He pointed out that an increase in price arising from the shortage of supplies of a particular commodity or service would prevent some people from obtaining it because they could not afford it, or would force them to do without other things. The Canadian government wished to prevent price rationing of goods and services which would allow goods to go to the highest bidders.

From the time of the institution of the over-all price-control policy, the government expected that subsidies would be necessary to hold the established ceiling.[9] It was not long before this necessity became real. The need for subsidies arose from two main causes.[10] First, some costs cannot be controlled. Import prices are determined by foreign exporters or by price-control authorities in foreign countries. Furthermore, the scarcity of shipping and the submarine menace has shut off many usual sources of supply and necessitated shifting to more expensive sources. As these cost-prices go up, it becomes less profitable to import goods or to purchase the high-cost substitutes. Second, a squeeze developed at the wholesale and retail levels because under the ceiling the prices at the different levels were not in a balanced relationship. In many cases, sales reflected prices of inventories purchased at some time previous to the base period. Between the date of purchase of the inventories and the base-period date, prices of replacements had risen.

If the ceiling prices were to be held, measures were necessary to absorb the increases in the uncontrolled costs and eliminate the squeeze. The squeeze was handled by a combination of methods.[11] The Wartime Prices and Trade Board adopted the policy of rolling back the costs from the retailer to the manufacturer. In some cases, however, the manufacturers and dealers together could not absorb all the squeeze. In such cases where supplies are regarded as essential, the government has undertaken to absorb a portion of the squeeze by means of a subsidy pending the working out of other methods to reduce costs.

The most important cases of uncontrolled costs have been in the field of imports.[12] The Wartime Prices and Trade Board expected

[10] *Ibid.,* p. 4.

[11] *Ibid.,* pp. 5, 8-9.

[12] *Ibid.,* p. 4.

originally that the chief need for subsidies would be to compensate for increased import prices. It was assumed that the over-all ceiling covering prices of domestic commodities and services, as well as wages and salaries, would prevent increases in costs from those sources and eliminate the need for price increases or subsidies except in special or temporary instances. The possibility that domestic subsidies may have to be granted on a broader scale than anticipated coupled with the institution of the over-all price ceiling in the United States may mean that the problem of subsidizing domestic production will become increasingly important while the necessity of large-scale subsidies for imports will decrease.

The general principles of the Canadian subsidy may be summarized as follows:[13] (1) Subsidies are paid for the purpose of keeping down the cost of living. They are paid to producers on condition that they maintain supplies and carry out the policy of the price ceiling by supplying goods to others at ceiling prices. (2) Subsidies are paid to maintain supplies of essential commodities only. Rather than subsidize unessential or luxury goods the Canadian government is willing to permit them to disappear from the market. (3) Under no circumstance is a subsidy permitted to constitute a special benefit to the subsidized industry or business firm. In order to qualify for a subsidy, an industry is required to show that it has instituted all possible economies and that its margin of profit is no more than reasonable or necessary. The industry receiving the subsidy must bear a part of the increased costs in respect of which the subsidy is paid. (4) The reduction of costs through standardization and simplification of the product and the elimination of unnecessary frills and services are expected to remove or greatly minimize the need for domestic subsidies.

The general policy with regard to the payment of subsidies has been determined by the government on the advice of the Wartime Prices and Trade Board.[14] Basic decisions needed to apply this policy are made by the board subject to the approval of the Minister of Finance. These decisions determine whether or not a particular commodity should be subsidized and by what methods. Details of each particular case are worked out by the particular administrators of the board concerned with the commodities or trades, aided by the Commodity Prices Stabilization Corporation, the government-owned company which serves as the agent of the board for the payment of the subsidies. The corporation pays the subsidies directly to importers or others entitled thereto or subsidizes indirectly through bulk purchases of certain commodities.

[13] *Ibid.*, pp. 4-6.

[14] *Ibid.*, pp. 5-6.

Subsidies have been paid on a wide range of imports including rice, cotton, wool, hides, grapefruit juice, dried fruits, and cotton fabrics.[15] Domestic subsidies are being or have been paid on milk, canned fruits and vegetables, leather footwear and leather clothing, and a list of about forty grocery items specified in Order No. 116 of the board, dated March 23, 1942.[16] The milk subsidy, however, was only a temporary measure and was discontinued at the end of April in favor of an adjustment of prices for milk products.

The cost of the Canadian subsidy has been surprisingly small. From the date of the institution of the over-all ceiling to June 2, 1942, the total cost was about 4½ million dollars.[17]

The British and Canadian experiences, thus far, point to successful use of subsidies as an aid to wartime price control. Experience with adjusting prices upward with changes in costs led the price-control authorities of those countries to abandon that practice and adopt firm price-ceiling policies. Although the British and Canadian wartime price situations are not entirely comparable to that of the United States, subsidies have been used to meet many of the same price-control problems prevailing in this country. In two respects the Canadian situation is much different from our own as Canada has ceilings on both wages and farm prices. Consequently, the need for subsidies to meet rising wage costs and rising agricultural prices has not appeared. The British have controlled retail food prices but have had to meet the problem of higher transportation costs on shipments of food products on higher farm and imported food prices.

The Need for Subsidies in the United States

The General Maximum Price Regulation established price ceilings for the bulk of the commodities and services which consumers buy but left many of the costs of producing these commodities free to move upward. Certain prices that enter into costs are not yet under the ceiling or are not controllable under the Emergency Price Control act. The prices paid by importers for imported commodities, the prices of raw agricultural commodities and wages represent uncontrolled costs in the production of many commodities which are themselves subject to price ceilings. Even if it were possible to control all factor prices, unit costs and margins could not be held rigid. Unit costs are not only a function of factor prices but also depend upon the physical

[15] *Ibid.*, p. 10.

[16] *Ibid.*, pp. 7-8.

[17] Office of Director of Public Information, Weekly Bulletin for United States Newspapers, Vol. II, No. 22 (June 7-13, 1942), p. 2.

conditions of production and distribution. For example, cost increases may be occasioned by the necessity of producers resorting to less efficient labor and other resources; or higher transportation costs may result from a shift from ocean freight to rail transportation. Thus any attempt to maintain a rigid ceiling on prices must provide for compensating producers and distributors for increases in unabsorbable costs if output is to be maintained. Subsidies need not, of course, compensate for every increase in the cost of production of commodities under the ceiling. But when these increased costs cannot be absorbed at one or more stages of production without losses or serious profit limitations, producers and distributors will not be able to continue to perform their functions; if the output of an essential commodity is to be maintained, the only alternative to raising retail prices is to subsidize the industry.

Recent experience in the United States with maximum price ceilings has revealed five general types of subsidy cases classified according to the reason why the subsidy is required.

1. *The Unabsorbable Squeeze.* By the unabsorbable squeeze is meant a reduction in margin resulting from the lag in adjustment between buying and selling prices that cannot be absorbed at one or more levels of production or distribution. A squeeze occurs when sellers set their prices at the time of the freeze on the basis of the average cost of their inventory rather than on the basis of replacement cost when the latter is higher. The squeeze can be *rolled back* to an earlier stage of production by requiring that stage to reduce its price to a lower level. If producers' costs have not risen substantially, it may be possible to require them to absorb all or a part of the squeeze on wholesalers and retailers by means of a roll-back; if producers' costs have also increased, it will be necessary to pay them a subsidy to enable them to reduce their prices to the dealers.

2. *Higher Import Prices.* Import prices represent an important group of prices ordinarily not subject to control. Even if the control of the actual prices charged by foreign sellers could be achieved, increased shipping costs and the necessity of getting the commodity from new sources may be responsible for substantial rises in the cost of importation. Actually, increases in the prices charged by foreign sellers have been few in number since the beginning of the year.[18] The cost of imported commodities has risen largely because of the increased war risk insurance rates and ocean freight surcharges, and the additional rail transportation charges resulting from the diversion

[18] The major increases in foreign sellers' prices since January 1, 1942, have been in the prices of Chilean nitrates and Australian wool.

of cargo from east coast ports to Gulf ports.[19] A part of the increase in war risk insurance is being absorbed by the War Shipping Administration which has been granting rates substantially lower than commercial rates. To the extent that losses are incurred by the War Shipping Administration, this involves a subsidy on imports.[20]

3. *Increases in Agricultural Prices.* Probably the greatest threat to the ceilings established under the General Maximum Price Regulation lies in the possibility of further increases in raw agricultural commodity prices. Until the prices of those commodities reach the minimum ceiling levels established by the Emergency Price Control act, they cannot be controlled by the Office of Price Administration.[21] Already breaks in the price ceilings for canned fruits have been announced and other ceilings are being threatened unless funds are provided to subsidize processors for increases in farm prices. Processors may be subsidized directly or the Commodity Credit Corporation can, as it has in the case of certain commodities, buy the raw commodities at market prices and sell them to processors at prices low enough for them to maintain their prices to the dealers. To subsidize agricultural commodities by an amount sufficient to allow farm prices to rise to the minimum ceiling prices established by the Emergency Price Control act without preventing a further break in OPA price ceilings would cost in excess of 3 billion dollars annually. It is quite important to prevent by the use of subsidies or by some other means a rise in the cost of feed grains because of the effect of an increase in the cost of feed grains on the value of meats. Assuming no change in the feed-meat ratios, a rise in the prices of feed grains to the minimum price ceiling levels for agricultural commodities would increase the farm value of meats by more than 50 per cent.

Assuming no change in the pattern of farm to retail price spreads,[22] a given increase in farm prices will result in a much greater increase

[19] War risk insurance rates on cargo from Brazil have risen from 1 per cent of the value of cargo to 15 per cent since the beginning of the year. The rates on cargo from India have risen from 3 per cent to about 25 per cent of the value of the cargo over the same period.

[20] The War Shipping Administration is also subsidizing the coastwise transportation of petroleum products.

[21] According to the Emergency Price Control act of 1942, Sec. 3 (a): "No maximum price shall be established or maintained for any agricultural commodities below the highest of any of the following prices. . . . (1) 110 per centum of the parity price for such commodity . . .; (2) The market price prevailing for such commodity on October 1, 1941; (3) the market price prevailing for such commodity on December 15, 1941; or (4) the average price for such commodity during the period July 1, 1919 to June 30, 1929."

[22] See Richard O. Been and Frederick V. Waugh, *Price Spreads Between the Farmer and the Consumer* (1936); See also, *Supplement* to 1936 Report (Feb., 1941).

in the retail value of farm commodities. This initial increase in retail value will interact on the parity index or the index of prices paid by farmers to cause a still greater increase in the minimum price-ceiling levels below which OPA cannot control farm prices.

4. *Increased Transportation Costs.* Transportation costs on several important commodities have increased sharply since the establishment of the general price ceiling in March 1942. These increases have resulted largely from the shift from water-borne to rail transportation, and the increases in the cost of shipping by water itself. Probably the most publicized case of an increase in transportation costs is the increased cost of shipping petroleum products to the east coast by rail instead of by tanker. This increase resulted in OPA's raising the price ceiling on gasoline by 2½ cents. Last August it became possible to rescind this price increase when the Reconstruction Finance Corporation agreed to subsidize the increase in transportation costs. The RFC is also subsidizing the increased costs of shipping coal to New England by rail instead of by water as was formerly the case.

5. *Subsidizing High-Cost Output.* Where higher than ceiling prices are necessary in order to obtain the output of high-cost firms or in order to obtain the marginal or high-cost output of efficient firms, it may be more desirable for the government to buy the marginal output at premium or above-ceiling prices and then resell at ceiling prices. For example, in the case of zinc, lead and copper, the Metals Reserve Corporation pays premium prices to firms for output above their assigned quotas, the quotas being established on the basis of that output which the firm can afford to sell at ceiling prices. Very efficient firms will have high quotas with very little of their output receiving the premium price; high-cost firms may have no assigned quotas but may be permitted to sell their entire output at the premium price. To the extent that the Metals Reserve Corporation resells the above-quota metal at the ceiling price it is subsidizing the high-cost output. Since the bulk of the metal is used for military production, the government itself saves many millions of dollars by paying a differential price for high-cost output as compared with the old bulk-line method in use during World War I.

In addition to the above types of subsidy cases, subsidies might be used to cover increased wage costs resulting from wage rate increases granted by the mediation or arbitration authorities. It would of course be unwise from the standpoint of price control to grant subsidies in every case where wage increases occur. In the absence of direct controls over factor costs, price controls must be administered so as to put pressure on costs.

The Economic Justification of Subsidies

The economic justification of a subsidy program designed as an aid to price control must be concerned with two important questions: (1) How do subsidies affect the distribution of income? (2) Are subsidies inflationary?

In considering the first question, it should be pointed out that a properly administered subsidy program should not constitute a benefit to the industries or firms receiving the subsidies. Subsidies should be paid for the purpose of enabling producers to continue producing essential commodities and at the same time to hold down or to reduce their prices in the face of higher costs. They should compensate for at least no more than the reduction in profit for which the imposition of price control is responsible. Where margins are sufficient to absorb cost increases without an unreasonable reduction in profits, subsidies should not be paid. If this principle is adhered to, subsidies will not increase the net profits of the firms receiving them as compared with what they would be if prices were allowed to rise.

Holding down prices by means of subsidies paid out of public funds makes for a more equitable distribution of essential commodities made scarce and more costly by wartime demands. When prices are allowed to rise, limited supplies go to those whose incomes are greatest. Equitable distribution requires that lower income groups should be on an equal footing with the wealthy in obtaining the essential cost-of-living commodities. Where supplies are so limited that the demand cannot be satisfied at existing prices, rationing should be instituted.

The question as to whether subsidy payments are inflationary has little meaning except in relation to the alternatives available, namely, either permitting the production of the commodities in question to be curtailed or perhaps eliminated entirely, or allowing a rise in prices. In some cases it may be better to permit production to fall or even to cease entirely rather than to subsidize production. If the productive resources of firms unable to continue operations without a subsidy were transferred to profitable firms, the value of their product would be at least equal to the income payments which they receive, while if these firms were maintained by means of subsidy payments, the income payments to the productive factors would exceed the value of their product. When the entire resources of firms can be transferred to more profitable use elsewhere, it is clearly not desirable to subsidize unless the particular output is critical. In such cases the payment of subsidies would be more inflationary than permitting the elimination of firms, since with subsidies, income payments to the productive

factors would be greater than the value of the output. Where resources are not transferable, subsidies will be more inflationary than allowing the firms to fail if the income payments to the productive factors amount to more than the value of the products. But in wartime, high cost production or the use of less efficient resources should not be eliminated simply because their employment adds to inflationary pressures. The primary objective must always be the maximization of production of war goods and essential consumers' goods.

Of greater significance for this discussion of subsidies and inflationary pressure is a consideration of subsidies as an alternative to a price rise for the commodity whose costs have increased. In one sense, a subsidy to keep prices down is less inflationary in so far as the subsidy program achieves its purpose, *i.e.*, actually holding down the level of prices. But in the face of a level of consumer demand in excess of the volume of goods available for civilian consumption at a given level of prices, maintenance of the price level may be only a short-run achievement; perhaps even a Pyrrhic one if the subsidy payments constitute a net contribution to the sum total of inflationary pressures as compared with the situation under a price rise.

The amount of inflationary pressure at any given time is used here to mean the excess of aggregate monetary expenditures on the part of consumers in any given period over the current production of goods available for civilian consumption during the same period valued at prices existing at the beginning of the period. Under rigid price control, inflationary pressure need not result in higher prices; it may simply deplete dealers' stocks at a faster rate than they can be replaced and hasten the day when general rationing will have to be instituted. The following analysis of the effects of subsidies as an anti-inflationary device first takes account of the *direct* or *immediate* effects of subsidy payments on inflationary pressure; and second, and perhaps more important from the standpoint of judging the value of a subsidy program, the secondary effects of subsidies designed to keep prices down.

Unless accompanied by increased taxation, government subsidies add to the total stock of purchasing power. There are, however, certain compensating factors in the use of the subsidy method as compared with that of permitting prices to rise, which should be explored before judgment can be passed even as to the direct inflationary effects of these two methods. In order to compare the inflationary effect of a subsidy payment with that of permitting a given price to rise, the total volume of purchasing power in existence for each case must not be the sole basis of comparison; the disposition of the purchasing power in the

two circumstances must also be taken into account. Let us assume that the total production of goods available for civilian consumption over a given period of time is fixed, but that the rate of consumption can be varied by increments or decrements to dealers' stocks. It will also be assumed that certain uncontrolled cost items have risen and that the government is faced with the alternative of either paying subsidies or permitting prices to rise. If by means of subsidy payments to the sellers, a given price is held down, consumers will be able to buy more goods with the same amount of money than they could if the price were allowed to rise. (If the demand for the commodity is elastic, consumers will buy more of that commodity at a lower price; if it is inelastic, they can buy more of other commodities.) If consumers maintain the same volume of money expenditures in both cases, sellers' aggregate receipts will be greater by the amount of the subsidy when the price is maintained than in the case where prices are allowed to rise.

On the assumption that the rate of subsidy per unit of sales is equal to the rise in price if the subsidy is not paid, sellers' gross margins will remain the same.[23] The bulk of the increase in sellers' revenue will represent increased cash from the sale of stocks at a faster rate than they can be replaced and, therefore, will not represent a net addition to consumer purchasing power. Subsidies under price control, therefore, do not represent an increase in inflationary pressure as it has been defined. Subsidy payments allow existing inflationary pressures to take the form of depletion of inventories rather than increases in prices, since under the assumption stated above aggregate money expenditures of consumers are not increased.

The above analysis makes certain assumptions which are open to question. First, there is the assumption that consumers will maintain the same volume of money expenditures out of a given level of money income regardless of the level of prices. But at a lower level of prices *real* income will be greater with the same money income. If the marginal propensity to consume (in *real* terms) is less than the average propensity to consume, money expenditures out of a given level of money income will be less at lower prices than at higher prices.[24]

[23] Since sellers will be selling more units at a lower price, aggregate net profits will actually be greater over a given period. But since sellers will be aware of the fact that they are depleting their stocks at a faster rate than they can replace them, they are likely to hold this increase as a reserve.

[24] The proof of the above proposition is as follows:

Let Ym = money income of consumers

" Yr = real income of consumers with rise in prices

" Cr = real consumption with price rise

" ΔYr = increase in real income if prices prevented from rising

Thus, if prices are prevented from rising by means of subsidy payments, inflationary pressure will be less than it would be if prices rose, provided that the marginal propensity to consume (in real terms) is less than the average propensity to consume, *i.e.*, provided that consumers tend to save a larger proportion of their real incomes as real income rises. The difference between money expenditures by consumers out of a given level of money income at higher and at lower prices will be larger the greater the difference between the average and marginal (real) propensities to consume.[25]

The assumption of a negatively sloped average (real) propensity to consume function appears to be quite reasonable under present

---

" ΔCr = increase in real consumption if prices prevented from rising
" p = price level before price rise
" Δp = amount of rise in price level
" Cm = money expenditures of consumers with price rise
" Cm' = money expenditures of consumers without price rise

Let $k = k(Yr) = \frac{\Delta Cr}{\Delta Yr}$, the marginal propensity to consume

$$Cm' = (Cr + \Delta Cr)p$$
$$Cm = Cr(p + \Delta p)$$
$$\Delta Cr = k.\Delta Yr$$
$$\begin{aligned} Cm' - Cm &= Cr.p + \Delta Cr.p + Cr.p - Cr.\Delta p \\ &= \Delta Cr.p - Cr.\Delta p \\ &= k.\Delta Yr.p - Cr.\Delta p \end{aligned}$$

$Cm' \rightleftharpoons Cm$ according to whether

$$\frac{k.\Delta Yr.p}{Cr.\Delta p} \rightleftharpoons 1$$

$$\Delta Yr = \frac{Ym}{p} - \frac{Ym}{p + \Delta p} = \frac{\Delta p Ym}{p(p + \Delta p)}$$

Substituting,

$$\frac{\dfrac{k.\Delta p\ Ym.\ p}{p\ (p + \Delta p)}}{Cr.\Delta p} = \frac{k.\ Ym}{Cr(p + \Delta p)}$$
$$= \frac{k.\ Ym}{Cm}$$

Let $e = e(Yr) = \frac{Cr,}{Yr}$ or the average propensity to consume

$$e = \frac{Cm}{p + \Delta p} \Big/ \frac{Ym}{p + \Delta p} = \frac{Cm}{Ym}$$
$$Cm = e\ Ym$$

Substituting,

$$\frac{k.\ Ym}{Cm} = \frac{k.\ Ym}{e.\ Ym}$$

Cm' will be less than Cm, when the marginal propensity to consume is less than the average propensity to consume

[25] The proof of this statement is as follows:

From note 24 we have, $\frac{\Delta Cr.\ p}{Cr.\Delta p} = \frac{k}{e}$

conditions. In a period of large money incomes and high rates of saving, consumers will attempt, at least in the short run, to maintain the same level of consumption with a rise in prices, thereby increasing their rate of money expenditures. The advantages to be gained from the decrease in inflationary pressure through maintaining prices by means of subsidy payments must be weighed against the greater rate of inventory depletion and the hastening of the time when rationing will have to be instituted. It should be pointed out, however, that whenever inflationary pressures exist, all efforts to maintain prices by direct price controls tend to channel existing pressures into a depletion of inventories as opposed to forcing a rise in prices. But as was shown above, the inflationary pressure accompanying a given level of income is likely to be less at lower than at higher prices.

In the above analysis the assumption was made that the rate of subsidy was equal to the potential price rise. This will generally not be true, since subsidies can be scaled down by the amount by which sellers' profits exceed a reasonable level. This means that under a subsidy program sellers' margins, and hence their gross profits out of which they pay wages and profits, will be less than if prices are permitted to rise. Total revenues of sellers will, of course, be larger by the amount of the subsidy minus the reduction in consumers' money expenditures over what they would be at higher prices; but with no increase in production, this increase in sellers' revenues will represent, as pointed out before, stock liquidation and will ordinarily not be spent but will be held in the form of idle balances or used to pay debts. To the extent that sellers use their additional receipts for making consumption expenditures, inflationary pressures will be larger, but such expenditures will ordinarily not be large.

Sellers' revenues will also be less under a subsidy program to the extent that the subsidization of costs at the point where the cost increases have occurred prevents the pyramiding of costs and prices.

$$\Delta Cr.p = \frac{k}{e} \, . \, Cr.\Delta p$$

$$\begin{aligned} Cm - Cm' &= Cr.\Delta p - \Delta Cr.p \\ &= Cr.\Delta p - \frac{k}{e} \, . \, Cr.\Delta p \\ &= Cr.\Delta p \left(\frac{e-k}{e}\right) \end{aligned}$$

$$Cm - Cm' = \left(\frac{Cm.\Delta p}{p + \Delta p}\right)\left(\frac{e-k}{e}\right)$$

Thus, money expenditures out of the same money income will be larger at higher prices than at lower prices according to the above relationship. This amount will be larger, the greater the difference between the average and marginal (real) propensities to consume.

Subsidy payments, at most, compensate only for the absolute increases in costs, while if these costs are allowed to be reflected in higher prices, there is the danger that retail prices may rise by the same percentage as the rise in costs.

Thus far only the direct or immediate effects of subsidies on inflationary pressures have been considered. But it is in their secondary effects that the dynamic possibilities of price controls reveal themselves. The fact that consumers' money expenditures out of a given level of money income are likely to be less if prices are prevented from rising, makes easier the essential function of closing the inflationary gap, unless one considers that a rise in prices constitutes a solution to the problem of the gap. To close the gap simply by permitting prices to rise not only defeats the purpose of an anti-inflationary program, but also generates forces which tend *ex ante* to widen the gap still further. To the extent that the rate of subsidy payments is smaller than the price rise which the subsidy program is designed to prevent, sellers' gross profits will be larger under a price increase. This fact will result in higher income payments. Moreover, the increase in prices will lead to demands for higher wages which, when granted, will further increase income payments. Higher retail prices may also result in higher farm prices, since retail prices enter into the calculation of the index of prices paid by farmers, which is used in the determination of the parity index for agricultural prices.

It has not been our purpose in this paper to present a complete discussion of the concept of the inflationary gap or of the methods by which it might be closed. It is our conclusion, however, that a carefully planned subsidy program designed to prevent price increases on account of increases in the cost of essential commodities is likely to be less inflationary than the alternative of allowing prices to rise. This conclusion may, of course, be readily disputed if one chooses to define inflationary pressure as any increase in real expenditures relative to the current supply of goods available for civilian consumption. But to hold to this definition of inflationary pressure would be to deny that closing the gap by means of a price rise is inflationary.

Washington, D.C.

THE FOUNDATIONS OF THE DEMAND CURVE

By SIDNEY WEINTRAUB

I. Introduction

Modern economic analysis might be dated as beginning with the intensified study of the forces of demand. The use of the demand curve has accompanied this development almost from the start. Nevertheless, despite the importance of this analytic tool there are few thoroughgoing discussions of the foundations on which the curve rests. Isolated remarks are found in abundance, especially so in recent years when the conventions of earlier practice have been called into question. It is probably time to integrate these remarks and to see where they lead: to contrast them to the older ideas and their end-results.

In the discussion, attention will first be devoted to the older, and more usual, views of the demand curve. Actually this amounts to an examination of Marshall's assumptions. For not only did he take the trouble to mention its grounding, in contrast to lesser luminaries, but he also did most to implant the curve in the general and professional consciousness, although not actually the first to use the concept.[1]

After surveying Marshall's ideas, stress will be placed on the major theme of the article, namely, of the interrelations among demand curves. Then, after consideration of some supplementary matters, a restatement of the assumptions on which the demand curve rests will be offered.

II. The Marshallian Demand Curve

Turning through Marshall's *Principles* for a statement of the assumptions on which he draws the demand curve we find them to be fourfold: (1) given tastes of the consumer; (2) given income in the hands of the consumer; (3) prices (and quantities consumed?) of other commodities given and constant; (4) the marginal utility of money to consumers

[1] Among those who antedated Marshall were Cournot, Jevons and Walras in content if not always in geometry. Yet I think the rôle attributed to Marshall is merited. But see the use made of the curves by Fleeming Jenkins, *The Graphic Representation of the Laws of Supply and Demand* (London: Series of Reprints of the London School of Economics, No. 9, 1931). Despite the recent resuscitation of this work it does not seem ever to have had a wide audience. Marshall, however, does refer to it. See his *Principles of Economics* (London: Macmillan, 1920), eighth edition, p. 476n.

also constant.[2] The first three conditions, we shall see, fix the position of the curve in the chart field. The fourth serves to settle its shape. Needless to add, some definite time period is in mind: it is only for this interval that the curve is descriptive. Let us consider each of the Marshallian premises in turn.

The first supposition, of given tastes on the part of consumers, can be readily appreciated and accepted without reservation. For only then can we draw the familiar downward sloping demand curve showing the various quantities that will be purchased at successive prices. Alterations in tastes imply a shift in the curve, a movement from one position to another. Decreased desire is thus always depicted by a leftward movement. Increased preference for the commodity will, on the other hand, move the curve to the right.

Naturally enough we must presume a given income in the hands of consumers before the individual's demand schedule for a commodity can be traced. No quarrel can be found with this premise either. In the vast majority of cases we should expect the demand curve to move to the right when income increases. Certain instances may be found, however, where rising income leads to a diminution in demand. Yet these cases may be referred to as the more extraordinary occurrences.

The third postulate of Marshall is that other prices are to be taken as constant while the full course of the demand curve for any specific product is sketched.[3] This, we shall find, leads to more vexatious issues and is the major interest of this article.

Long ago, Marshall taught that the demand curve for tea will be of a certain order when a high price rules for coffee and, on the other hand, will contract when the price of coffee falls lower, other things the same. Marshall insisted, therefore, that the demand curve for closely rival products, or substitutes either in production or consumption, cannot be drawn unless the price of the related commodity is taken as constant throughout the curve tracing.

Now this procedure does seem reasonable. At the same time the assumption must profoundly affect the use of the demand curve from the standpoint of problems of monopolistic competition. For these are the very instances in which sellers are competing by making ready for market exceedingly close substitutes.[4] Indeed, apart from a few highly

[2] Statements of these conditions may be found scattered through the following sections and pages of the *Principles:* Book III, chaps. III and IV, pp. 95, 100-101, 109 and 132; also Mathematical Appendix, note VI, p. 842. *Cf.* also A. L. Bowley, *The Mathematical Groundwork of Economics* (Oxford: Clarendon Press, 1924), pp. 26, 50, 52, 54, 58. Bowley is more explicit on the assumption of other quantities also constant. At the least it is implicit in Marshall's fourth postulate.

[3] Marshall, *op. cit.*, p. 100.

[4] See Chamberlin's article "Monopolistic or Imperfect Competition?" *Quart. Jour. of Econ.*, Aug. 1937, vol. li, pp. 570-72.

restricted cases the demand curve, if it must be based on this assumption, would be useless. With rivals selling narrowly differentiated products it would only rarely be the case that their price will remain constant while the "price-innovating" seller varies his sales terms. The assumption must be viewed as unrealistic.

Although the inadequacy of the third postulate would be enough to destroy the widespread use of the Marshallian demand curve for problems of monopolistic competition—although not a family of curves as Chamberlin has shown[5]—we are not thereby released from analyzing the meaning and rationale of the final one, namely, the hypothesis of a constant marginal utility of money. We shall find, however, that it also requires the previous assumption along with it. This may be delved into further.

As are all marginal utilities, the marginal utility of money is defined as the addition to total utility made by an increment or a further unit of money.[6] Inasmuch as at the margin the desire for money is equated to the desire for goods,[7] the marginal utility of money can be measured by the additions to total utility made by the goods which a further increment of it can purchase.

In equilibrium, for all consumers, the marginal utilities of all goods purchased are proportionate to their respective prices. This is essentially the condition of equilibrium.[8] If one good sells for 10 cents and another for 20 cents and both are purchased, the latter must afford twice the satisfaction of the former. Otherwise, there would be the incentive to switch purchases one way or the other.[9]

Thus where commodities X, Y, Z . . . are purchased, $\frac{MUx}{Px} = \frac{MUy}{Py} = \frac{MUz}{Pz} = K.$

These ratios of the marginal utility of commodities to their respective prices reflect the marginal utility of money, K. They indicate the

[5] Edward Chamberlin, *The Theory of Monopolistic Competition* (Cambridge: Harvard Univ. Press, 1938), 3rd ed., pp. 90-93. Also a recent article making use of the same device, A. Smithies, "Equilibrium in Monopolistic Competition," *Quart. Jour. of Econ.*, Nov., 1940, vol. lv, no. 1, pp. 97-98.

[6] Marshall, *op. cit.*, pp. 95-96.

[7] For a clear formulation of this, despite the fact that the thought is embraced today by the leading writers on monetary theory, see J. R. Hicks, "A Suggestion for Simplifying the Theory of Money," *Economica*, Feb., 1935, N.S. vol. ii, no. 5.

[8] See Marshall, *op. cit.*, p. 95. Or any of the more thoroughgoing statements of *Principles, e.g.*, Wicksteed, Wicksell, Hicks, Pigou, etc., neglecting the more mathematical writers.

[9] This, of course, is not to say that the absolute amount of utility received by different consumers is the same. This would be a false deduction.

incremental importance that another unit of money would have.[10]

Holding K constant in drawing the demand curve for X, therefore, can be interpreted to mean any of the following things: (1) the total amounts consumed of all other commodities, Y, Z, . . . , and their prices, remain absolutely rigid as the price of X and its consumption varies along the course of the demand curve; (2) the marginal utility of the same stocks of other goods, Y, Z . . . , as formerly are affected when Px varies but offsetting movements in Py and Pz keep the ratios constant; (3) both quantities and prices of the other commodities vary while we move along the demand curve for X, but their variations are just sufficient to keep the ratios constant.[11]

Any of these interpretations might be placed on the Marshallian supposition. But it is apparent that senses (2) and (3) conflict with the second demand postulate, of other prices constant. They cannot have been intended. Furthermore, should either of them be the meaning attached, we would inevitably have to investigate intermarket relations as the price in one market varied. But these were the very problems that Marshall wished to avoid.[12]

Even the first sense, Marshall unequivocally stated, was an appropriate and serviceable one only when the amount spent in any one market formed a small part of the individual's total expenditure. Repercussions in other markets could then be safely neglected, as "of the second order of smalls." This would be the more true especially when, as he suggested, only minor deviations on one side or the other of the ruling price had to be considered.[13]

Let us see now the function performed by this hypothesis. Marshall wanted to exhibit the movement in the demand for X of a fall in its price. Thus as Px falls with Py constant, the consumption of X must

[10] This definition may be found in many writers: Marshall, *op. cit.*, Mathematical Appendix, p. 833; Bowley, *op. cit.*, p. 55; J. R. Hicks, *Value and Capital* (Oxford: Clarendon Press, 1939), Mathematical Appendix, p. 305; Henry Schultz, *The Theory and Measurement of Demand* (Chicago: Univ. of Chicago Press, 1938), p. 34; Vilfredo Pareto, *Manuel d'Economie Politique* (Paris: Marcel Giard, 1927), Mathematical Appendix, pp. 579, 585, to name but a few sources. It was this assumption of constancy in K that furnished Pareto with a continual base for attack on Marshall. Through voiding it in his new, important contribution, Hicks has been able to widen the scope of modern value theory.

[11] M. Friedman, "Professor Pigou's Method for Measuring Elasticity of Demand from Budgetary Data," *Quart. Jour. of Econ.*, Nov., 1935, vol. l, pp. 153-54, offers slightly different interpretations of a presumedly separate use of the idea of constancy in the marginal utility of money by Pigou. See, however, the latter's reply and a note by N. Georgescu-Roegen, in the same journal, May, 1936, pp. 532-39.

[12] *Cf.* Hicks, *op. cit.*, p. 12. For clearly Marshall's assumption means a unity elasticity of demand in the market reviewed and no ramifications elsewhere; that was why he adopted it. See Schultz, *op. cit.*, p. 48.

[13] See Marshall, *op. cit.*, p. 133.

inevitably expand in order that the utility-price equilibrium ratios be satisfied.

Hence Marshall was able to give a forthright explanation of the downward-sloping demand curve. There can be no gainsaying the fact that Marshall was always aware of the nature of his assumption even though it was not so discernible to many of his followers through the years. He suggests that only in a few practical cases, as the famous Giffen case and that of the supply of labor, would the hypothesis be inappropriate.[14] Scientifically he could thus proceed directly to the final results without the mass of explanation that would be required in taking into account movements in the marginal utility of money. In the end either such movements would merely confirm the conclusion reached more immediately or they would yield *curiosa* interesting solely to the theorist.[15]

Let us see what might happen if the marginal utility of money increased, or Y, Z . . . etc., increased in relative importance as the price of X fell. The income saved by the fall in price of X would leave a sizeable margin for expenditure. Subsequent rearrangement in the outlay, the buying of more Y, Z . . . at constant prices might lead to less need for X: a decreasing amount might be purchased, despite the fall in price, in order to keep the utility-price ratios in line. Demand for X would decrease as its price fell.

In case of a fall in the marginal utility of money as the price of X fell, there would be an excessive expansion in the demand for X. There would be a switch from Y, Z . . . to X. Decidedly the demand curve would be of normal form. But at the same time repercussions in other markets would be important and could not be precluded.

Believing both of these cases to be unusual, or a belief in the normal impotency of the income effect, as Hicks has recently dubbed the rearrangement of expenditure consequent upon a change in real income,[16] led to the Marshallian device and simplification. There is no reason why Marshall need be followed here. His demand curve follows readily enough from the first three postulates. This last one was designed merely to account for its normal shape. At the same time it avoided market interrelations. Seldom, we can admit, will the demand curves differ from the patterns sketched by Marshall. Since these anomalies do occur we need not *a priori* assume them away.

[14] *Ibid.*, pp. 132, 335-36. *Cf.* also Hicks, *op. cit.*, pp. 35-37.

[15] As Marshall probably would regard preoccupation with anything other than the normal shaped demand curve. *Op. cit.*, p. 132.

[16] Hicks, *op. cit.*, pp. 31-32, and *passim*. In indifference curve analysis the assumption of a constant marginal utility of money would mean a shift in demand to X from Y and Z as the price of X fell, due to the substitution effect, while the income effect would work to restore the original demands for Y and Z.

On the other hand, there is absolutely no reason why we should accept the device in so far as it amounts to a refusal to recognize and deal with market interrelatedness. For this must be handled in modern analysis.

III. The Inadequacy of the Marshallian Construction

Let us review the relevance of the Marshallian demand curve to a typical problem of current economic analysis, namely, the equilibrium of the firm, emphasizing its relation to the rest of the economic system. Each firm is conceived to produce a commodity for which rivals can only offer substitutes of a near or remote degree. Differences among commodities may be technical, geographic, or psychic; the latter differences are those viewed by consumers, whether the basis be real or factitious.

In the demand for the firm's product, the first two assumptions of Marshall carry ready assent. Tastes and incomes must be postulated. Of the remaining two postulates, that of the constant marginal utility of money can be dispensed with immediately.

This leaves us with the necessity of reconsidering solely the assumption of other prices constant while drawing the demand curve for a commodity X. It has already been said that this is at the height of unreality for the world currently envisaged by the economic theorist.

Suppose all firms were adapted competitively to the existing demand, therefore equating marginal costs and prices. Let us say that one firm suddenly decides to raise its price to exploit what it now recognizes to be a monopolistic position. Let us sketch the consequences.

Two possibilities emerge. Demand may be found inelastic. The rise in price will inflate the firm's gross proceeds. Either the demand for other goods will contract or consumer savings will diminish.[17] As close substitutes of a good in inelastic demand are unlikely, prices of other goods should show a sagging tendency.

In a world of close substitutes the more likely possibility is that demand will be found to be elastic.[18] The higher price charged for the article will stimulate a shift in demand to neighboring products. There should be a tendency for an immediate rise in prices, a tendency which would be reinforced through time by mounting marginal costs.

Converse movements would mark a fall in the price. Nearby sellers would have to lower their prices or see an excessive decrease in the quantity demanded.

[17] There is a point of interest here for business cycle analysis. See N. Kaldor's handling of kindred matters in "Speculation and Economic Stability," *Rev. of Econ. Studies*, Oct., 1939, vol. vii, no. 1.

[18] *Cf.* A. C. Pigou, *The Economic of Welfare* (London: Macmillan, 1932), 4th ed., pp. 259-62.

In all of these cases the assumption of other prices constant is a gross misfit. To continue to use it would be to remain blind to the phenomena.

Thus, if the demand curve is to be drawn on the assumption of other prices constant, its usefulness for economic analysis is either negatived or, at the least, seriously impaired. And the same criticism applies to the device of drawing a family of demand curves each attached to a separate price of the rival's product. For only one point on each curve is consistent with the rival's price policy: to draw the full course of the curve is to intimate that all price-quantity points are possible adjustments when, as a matter of fact, they are not.[19]

Unless a demand curve can be drawn on the assumption of other prices adjusted to compatibility with that named by the firm under review, it seems that this time-honored apparatus of economics must, if not disappear from the literature, play a rôle much subordinate to its position in the past. Ordinary ideas and topical treatment would have to be extensively revised. Simplified economics would be well-nigh impossible.

Now there are intimations in the literature that demand curves need not of necessity be drawn on the assumption of other prices constant. Indeed we need not go beyond Marshall himself to affirm it. In a footnote—as is so often the case in his work[20]—Marshall observed: "We must however remember that the character of the demand schedule for any commodity depends in a great measure on whether the prices of its rivals are taken to be fixed or to alter with it."[21] The inescapable inference is that the assumption of other prices constant is not strictly necessary.[22]

Hicks apparently concurs in this view. In a passage which is seldom iterated he argues that the demand for any product may be examined under either of two assumptions: (1) that other prices are given, or (2) that other prices are adjusted as to preserve equilibrium in their markets, given the price in the market under review.[23] Moreover, he affirms that the latter is the more important investigation. It should be

[19] See the previous reference to this construction of Chamberlin, n. 5 above. The criticism would have to be amended only for the very short run or "frictional" interval in which rival's prices are constant. But then the appropriate contrast is that between the short- and long-run demand curves: only one curve is pertinent to a given time interval.

[20] *Cf.* J. M. Keynes, "Alfred Marshall," in *Essays in Biography* (New York: Harcourt Brace, 1933), p. 205.

[21] Marshall, *op. cit.*, p. 105n.

[22] This is the sole time Marshall makes this point so far as I can see.

[23] Hicks, *op. cit.*, p. 66.

noted that the alternative formulations of demand are the very ones staked out by Marshall.

Mrs. Robinson too was inclined to this second view of the demand curve. Yet she never pushed the argument very far. Instead, she asked that for her work we merely admit the demand curve can be drawn without passing on its ultimate nature.[24] On the other hand, Chamberlin actually gave a demonstration of how such a demand curve might be derived. Yet he recognizes it as contrary to usual ideas and refrains from calling it a demand curve; he refers to it instead as a new type which stems from the "usual" demand curves in his parametric representation, the curve family drawn on the Marshallian condition of other prices constant.[25]

With these theorists apparently in agreement on the possibility of drawing a demand curve—or something very reminiscent of it—even on abandoning the hypothesis of other prices constant, the matter deserves closer scrutiny.[26] Needless to say it jars the common workaday ideas.[27]

IV. Interrelations of Demand Curves

Each monopolist with power to name the price for his product, despite the occasion of substitutes, and without fear that demand will suddenly contract to zero, will nevertheless continually bear in mind the resistances largely in the shape of the rival's price policy to any price movement he makes.

To illustrate the interdependence of demand and price for two closely related substitutes, A and B, let us suppose as before that both sellers are originally in competitive equilibrium, adjusting price and marginal costs. As a simplification we assume constant costs in both lines.

[24] Joan Robinson, *Economics of Imperfect Competition* (London: Macmillan, 1933), p. 21. On this basis she is able to proceed with her characteristic problem, the equilibrium of the firm, without bothering with market interrelations.

[25] Chamberlin, *op. cit.*, p. 90.

[26] Edgeworth states, without further explanation, that the postulate "might be dispensed with." Oddly, he supports its retention so as to secure "that exact correlation between the demand curve . . . and 'consumers rent.'" See his "Demand Curves," *Dictionary of Political Economy* (Palgrave, ed.), vol. 1, p. 543. Likewise Professor Robbins argues that the curve is germane not to the static world of "other things unchanged" but to comparative static analysis. See "Remarks Upon Certain Aspects of the Theory of Costs," *Econ. Jour.*, Mar., 1934, vol. xliv, no. 173, pp. 8, 10. For more recent statements see P. M. Sweezy, "Demand Under Conditions of Oligopoly," *Jour. of Pol. Econ.*, Aug., 1939, vol. xlvii, no. 4 and M. Bronfenbrenner, "Applications of the Discontinuous Oligopoly Demand Curve," *ibid.*, June, 1940, vol. xlviii, no. 3.

[27] Even as recent and modern a work as R. G. D. Allen's *Mathematical Analysis for Economists* (London: Macmillan, 1938), p. 109, makes the assumption of constant prices quite explicit in drawing the demand curve, to mention only one of the more rigorous treatments of economics.

In Figure 1 the demand for A's product is OM at the ruling price OL_1. The demand for B's commodity, shown in Figure 2, is Om, and at the ruling price Ol_1. The demand can thus be represented by a simple bar line at the pertinent price, extending out to the corresponding output.

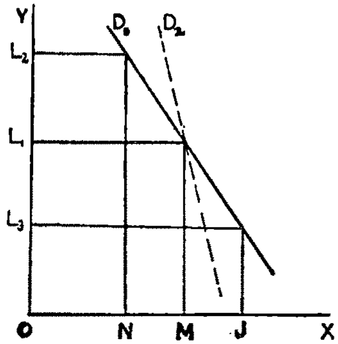

FIG. 1

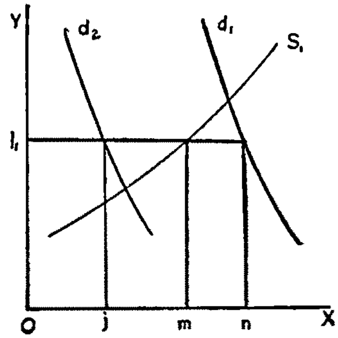

FIG. 2

Let us say that A comes suddenly to understand the nature of his control over price and decides to take advantage of it. He perceives greater profits by acting "monopolistically."

Price is raised to OL_2. Now a full demand curve can be drawn for B, depending on the price OL_2 in A. This curve is lettered d_1 in Figure 2. Quite clearly it is drawn on the usual principle of other prices, as that in A, being constant. Accepting the presence of constant costs in field B, and at the height Ol_1, the expansion in demand there results solely in an enlargement of output, by mn to On, as B continues to adjust price and marginal cost.

The demand for A cannot help but fall off: its price has risen relatively to B. With B's price constant at Ol_1, the demand for A comes to settle, say, at ON.

And in this manner we can proceed. For prices higher than OL_2 in A, demand curves further extended than d_1 in B can be drawn. Output will expand there. A's production, in contrast, will contract.

To complete the illustration we can visualize the monopolist A actually lowering his price below OL_1, the original adjustment, say to OL_3.

Demand in B would now fall back to d_2. Continuing the assumption of constant costs there, and therefore a rigid price at Ol_1, the quantity sold in B amounts to Oj. The amount sold by A, in contrast, is elongated to OJ.

Thus for every price in A, there is a new adaptation in B. Separate demand curves can be drawn there for every new price in A. But let us

look meanwhile at what has been accomplished for the A firm. Running a smooth curve through the coördinates at the end of each bar line showing the amounts that are wanted at various prices OL_2, OL_1, OL_3 . . . , we derive a locus suspiciously resemblant to the normal shaped demand curve. But now it is drawn not on the assumption of other fields unaffected—the usual Marshallian assumption—but instead of full adjustment elsewhere. In this respect it is an innovation.

Let us remove the hypothesis of constant costs in B. It has served its simplifying purpose. Its abandonment will hasten an extension of the argument.

Suppose costs in B can be depicted by the rising cost curve S_1. Thus when A's price goes to OL_2, and demand in B to d_1, the expansion in demand will expend itself partly in raising the price in B and partly in extending output. The sharper the price rise—or the more inelastic are costs in B—the smaller will be the contraction in demand at firm A. In the contrary case, imagine the price in A lowered to OL_3. The backward shift in demand for B to d_2 will engender a lower price there. The expansion of sales in A will be damped.

Once more, using the original coördinates at OL_1 and OM as a pivot a smooth curve—the dashed line D_2—can be traced out in Figure 1, showing the quantities of A's product that will be taken off the market given the rising cost curve S_1 in B. It offers an obvious contrast to D_1 which conceived of only quantities, and not prices, being affected in B.

Certain instances in which cost conditions in B are falling might also be described. Here an expanded demand will lead to a price fall. This would tend to make the demand for A at higher prices so elastic as to practically enforce the competitive (or previous) adaptation: monopoly power to raise prices would be practically nil. Should A lower his price, however, either B could be forced out of business by the losses imposed, or otherwise would have to raise his price. For the system as a whole this would act as a counterweight to the fall in A's price.

In all of these instances there is the one point which deserves very especial emphasis. It is this: *Not until price and output adjustments elsewhere are known will the sales of the A firm be determined.* The quantity demanded is thus dependent upon the full general adaptation.

We have therefore derived a demand curve which relates each point on its locus to an entirely different total adaptation, to a separate and distinct general equilibrium. There is at least one further point to be touched upon before proceeding to give some samples of the versatility of the new assumption of full adjustment elsewhere to any price of the firm under review.

It was assumed for the B firm, in Figure 2, that it merely accepted

the price ruling in A as a datum and then passively adjusted its own price and sales to the forthcoming demand. Indubitably this would be descriptive if B signified a competitive industry. But let us examine the consequences if it does not permit itself to be led in this way.

One way of resolving the problem would be by drawing "price reaction" curves and then considering whether there is a point of mutually satisfactory price relations.[28] And only that price could rule for any extended period: it alone would offer hopes of a stable equilibrium. Yet we are still not precluded from drawing a demand curve for each firm on the principle suggested, namely, each coördinate apposite to a distinct price and output elsewhere. With this in view, let us look at some demonstrative problems, some applications of the idea developed above.

Imagine first that, as our firm A varied its price, nearby sellers did likewise, lifting their prices proportionately. Should they have left their prices unchanged the demand for A would have been, say, the dashed line D_1D_1' in Figure 3. However, with A's price movement met by the

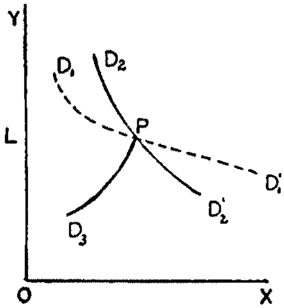

FIG. 3

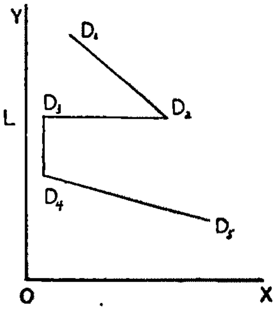

FIG. 4

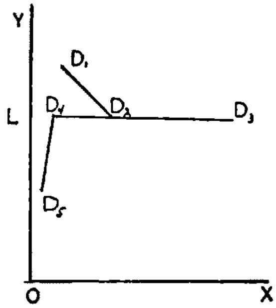

FIG. 5

other sellers, the demand curve for A is now D_2D_2', the solid line. More than before can be sold at the higher prices, above OL, inasmuch as B's prices (rival sellers), are also higher. The converse is true of prices in the lower regions below OL.

Suppose now that for prices above OL no reactions from rivals are encountered. However, for prices below OL, A's price oscillations are met. The demand curve to describe this would run from D_1 to P and then to D_2' or D_1PD_2', with the sharp corner at P.[29]

Or it may be that rivals are opposed to a price cut by A and take steps to counter it, lowering prices by 10 per cent for every 1 per cent fall at A. The demand curve would thus bend backward at P to D_1PD_3.[30]

[28] See Smithies, *op. cit.*, pp. 107-15.

[29] *Cf.* P. M. Sweezy, *op. cit.*, pp. 569, 571.

[30] *Cf.* Bronfenbrenner, *op. cit.*, p. 420-27.

Perhaps no reaction will be found for a price above OL, but for a price below this a large rival will not only meet it, but will also engage in an advertising and product variation campaign. A may either be unwilling or unable to undertake counter measures. Demand for A's product would take the queer form traced out by $D_1D_2D_3D_4$ in Figure 4.

For conventionally priced commodities a demand curve as in Figure 5 might be applicable. At prices above the customary figure of OL, demand falls severely: at prices below this figure rivals again counter by advertising or by a product variation favorable to consumers. For example, the weight of the product might be increased, though the price remains constant. Commodity A at the lower price may receive a reputation for "cheapness" or inferiority. An odd shaped demand curve like $D_1D_2D_3D_4D_5$ in Figure 5 can be traced.

And so we can proceed to draw demand curves of any shape whatever. The sole limitation seems to lie in the ingenuity of the analyst and the facts and reaction patterns of the real world. At the same time the normal Marshallian demand curve emerges as a special case, an exceedingly simple one in which rival reactions are of a single form: it pertains to the world of competition and constant costs. This, therefore, becomes the relevancy of the mass of demand curves drawn in economic literature. To continue the restriction is needlessly to hamper further analytic development.

If we are in the habit of calling the schedule drawn on the assumption of other prices constant the "demand" curve, there remains the terminological matter of referring to the new curve of final adjustment. Probably it would be simplest, and conform most to what will be done in any event, to continue to call it the demand curve, while emphasizing that no longer is it drawn on the Marshallian *ceteris paribus* but rather on a *mutatis mutandis* basis for the rest of the economic system.[31]

V. Subjective and Objective Demand Curves

Recently certain writers have argued that the demand curve had to be conceived as a subjective or imagined phenomenon. Its existence was supposed to reside in the seller's mind. Hence, it was argued, it could attain any form, be based on any premises. It could be postulated without further ado. So long as the seller thinks things are so, the curve reflects his mental state.

Now the foregoing argument has tended to confirm the view that the curve can partake of any shape whatever. Yet all along, discussion has proceeded as if the demand curve was an objective affair, the epitome

[31] Bronfenbrenner refers to the curves in this way in a footnote.

of reality. This apparent contradiction had better be resolved.[32]

Ostensibly, it is the subjective or *ex-ante* demand curve that is the basis for the producer's adaptation. Output hinges upon it. However irrationally it be conceived, however illogical its foundations, it is on the basis of this curve that the entrepreneur makes his price and output decision under monopolistic competition. The curve itself requires no further analysis. Furthermore, however inconsistent they be, separate curves can exist simultaneously in each producer's mind.

Nevertheless, in order that market equilibrium persist, that the *ex-ante* or planned price-output adaptation be a determinate one and able to continue through time, it must conform to and be consistent with certain objective conditions. Briefly, for the planned adaptation to eventuate, the position chosen must be compatible with a point on the objective, or actual, market demand curve. Otherwise the planned output will finally turn out to be too large or too small; price will be too high or too low. For expectations to be fulfilled correctly, at the output of *ex-ante* equality of marginal revenue and marginal costs the imagined or prospective demand curve must be identical to, tangent to or intersected by the market or objective demand curve. For full equilibrium, moreover, at the same planned output, average realized costs must be equal to those expected, to the *ex-ante* costs.[33]

Thus there are the two demand curves, and the conditions of compatibility between them are those stressed. Admittedly our discussion has been directed to the objective curve, the one that could be known at market time or from a retrospective view of the market state. It is this curve which entrepreneurs try to prognosticate, however imperfectly they do so. It is this curve which would be duplicated in their minds under conditions of perfect foresight. Unless entrepreneurs do foreshadow its course their adaptation will yield them less than maximum profits.

[32] For a fuller argument, see my article, "Demand Anticipations and Monopoly Equilibrium," *Jour. of Pol. Econ.*, Vol. L (June, 1942).

[33] Planned price and sales will thus depend upon the equation of prospective or *ex-ante* marginal revenue and costs. For the plans to be fulfilled the following equalities must hold:

$$AR_a = AR_r \text{ and } AC_a = AC_r.$$

where AR refers to average revenue, AC to average cost and the subscript $_a$ to anticipations and $_r$ to realized conditions. For the position to be fully stable, for a movement above or below equilibrium output, the following inequalities must hold:

$$AR_a > AR_r \text{ and } AC_r > AC_a.$$

That is to say, in revenue and in costs disappointments must be encountered in order to drive the monopolist back to the original equilibrium. Or, if there is a pleasant surprise in one respect, it must be counterbalanced by disappointment in the other. In the latter event the stability condition might be stated as dependent upon whether:

$$AR_r - AR_a \overset{>}{\underset{<}{=}} AC_r - AC_a.$$

Both concepts of demand have their place in economic analysis. One calls for little explanation, the other for an extended statement. Still, should entrepreneurial plans be at all broadly conceived, the subjective curve would have to include the same fundamental elements as comprise the objective curve. The former curve is appropriate for an insight into the motives or forces determining entrepreneurial behavior. The market or actual curves would be relevant for propositions on economical activity, on how far it has deviated from the competitive norm as a fact, and on how well or poor a job the entrepreneur has done in forecasting market conditions.[34] Finally the two curves must be considered concomitantly in matters concerning the determinacy and stability of equilibrium.

VI. The Foundations of the Demand Curve

We may now offer a more positive statement of the bases on which the demand curve rests. We saw already that of the Marshallian postulates the first two went unquestioned. Now, as before, the assumption of given tastes must be admitted. Any alteration in tastes will shift the demand curve one way or the other.[35] Again, with respect to consumer's income, this too must be postulated. We turn now to the more difficult matter of the assumptions which must be made with respect to prices.

At the outset, we might acknowledge a point unmentioned until now. Consumer views on future prices must be part of the components of present tastes or desires. In the expectation of higher prices present demand will be enlarged; and vice versa.[36] For this study, this barefaced mention will suffice.

We have already seen that with each price named by our seller, a new and distinct curve of demand would confront every other firm in the field. The output that could be sold by the price-innovating firm was indeterminate until the final price and output adaptations of the others were known. Each point on a firm's demand curve was effectually related to an entirely distinct set of prices in the rest of the economic system. Each price was therefore related to an entirely separate general equilibrium.

[34] *Cf.* J. R. Hicks, "The Foundations of Welfare Economics," *Econ. Jour.*, Dec., 1939, vol. xlix, no. 196, p. 708.

[35] The advertising policy of the firm is also a factor in shaping current tastes.

[36] On the other hand, entrepreneurial expectations of the effect of present prices on future demand will determine their present output and price policies. *Cf.* A. Marshall, *op. cit.*, p. 317, and for the more recent restatements and extensions of his ideas, see C. Roos, *Dynamic Economics* (Bloomington, Ind.: Principia Press, 1934), chap. viii; Allen, *op. cit.*, pp. 434-38, 533-36; Mrs. Robinson, *op. cit.*, pp. 22-23; R. H. Coase, "Some Notes on Monopoly Price," *Rev. of Econ. Stud.*, 1937-38, vol. v, pp. 22-25.

On this view the hypothesis of constant prices in the rest of industry becomes peculiarly relevant to the simple world of perfect competition and constant costs. Should other sellers react with price policies of their own, or should costs be other than constant, it is no use to work the fiction that their prices are "unchanged." In so far as their prices are changed, the quantities demanded of a seller will be quite different than if their prices were actually constant.

Not alone need we include the price and output adaptations of other sellers as part of the total forces shaping the demand curve for each firm, but it is also necessary to include their advertising and product variation policies as the price of our one firm alters. For, in so far as these elements do vary with movements in the price of the firm under review, demand for the latter's product will be either extended or contracted. Reaction of other sellers with respect to these two variables must also be premised along with their ordinary price reactions.

Based on these factors, demand curves no longer remain simple affairs and no longer evidence simple, straightforward forms. Restrictions on their shape become practically nil. Almost any drawing will suffice so long as it is accompanied by an adequate description of the factors responsible. We should expect that normally the Marshallian drawing will serve. However, we should not be surprised when, in investigating a particular market, something totally different eventuated.

Saving, Investment, and Technological Unemployment

Two papers in American economic journals of the past eleven years have addressed themselves exclusively to the correction of errors in the prevailing analysis of technological unemployment. It is unfortunate that the second,[1] which makes a definite contribution, should have ignored the contribution of the first.[2] It is also unfortunate that the second, written in the post-Keynesian period, should have failed to apply to the problem at hand the theory of saving and investment as determinants of employment.

Technological advance which permits production of a given quantity of goods with the use of a reduced quantity of some productive agent or agents (say, labor) concentrates a given flow of purchasing power[3] into fewer hands. Where this results in an increase in the volume of saving—which we may take to be the general but by no means necessary case—an increased volume of investment will be necessary to maintain even the new lower level of employment. A still larger increase in investment will be needed to restore the old level of employment. Surely here, and not in any consideration of fixed capital as parameter[4] or circulating capital as sustaining force,[5] lies "the key" to understanding of technological unemployment. (To this "key," of course, must be added the clue, adequately exposed by Neisser, that increased demand for

[1] Hans P. Neisser, "'Permanent' Technological Unemployment," *Am. Econ. Rev.*, Vol. XXXII (Mar., 1942), pp. 50-71.

[2] Alvin H. Hansen, "Institutional Frictions and Technological Unemployment," *Quart. Jour. of Econ.*, Vol. XLV (Aug., 1931), pp. 684-97. Reprinted as chap. X of Hansen's *Economic Stabilization in an Unbalanced World.*

[3] A given number of monetary units, that is. If prices are reduced, their real value will be greater.

[4] Neisser's argument that the quantity of fixed capital is of peculiar importance (given the state of techniques existing at the moment) in limiting employment seems totally untenable. See *op. cit.*, p. 61 and Section VII. Certainly the most that can be said is that bottlenecks may develop in one type or another of fixed capital as well as in one type or another of circulating capital or of human skills. Fixed capital is not a special genus.

[5] Neisser attacks the argument that so long as the wage fund is maintained technical advance will not cause unemployment. However, this section of his paper (Section IV) is both illuminating and confusing, the latter because he uses the same term in different senses. He refutes classical theory by a discussion concerning working capital which uses the term at successive moments to refer to a stock of wage goods, to technical equipment, and to money costs. Thus the argument (pp. 61 and 62) that working capital (wage goods) will not be set free by technical advance even if laborers are displaced, because if output increases more working capital will be needed. Nevertheless, its value may fall because the enterpriser will pay out smaller sums to factors!

goods may result in higher prices of goods or greater demand for other factors, rather than in reëmployment of labor.)

If the technical advance results in price reduction, purchasing power of the existing monetary flow will be increased. However, since the addition is only a single injection its effect will taper off, and the system, barring secondary effects of the shift in price relationships, will approach a new level of employment and income lower than the original one.

This theory of technological unemployment may be applied not merely to labor but to any factor or group of factors. For any one factor out of a group displaced, a further elaboration is necessary. The shift in purchasing power between individuals implies both a change in the volume of saving and a shift in demand. This shift in demand will cause a change in the employment of the agents displaced, in addition to that caused (1) by the original technological displacement and (2) by the change in the volume of saving. The change associated with the shift in demand will be positive, zero, or negative for any one factor, depending on whether that factor is employed in greater, equal, or smaller proportion in producing the good for which demand has increased than in producing the good for which demand has decreased.[6] (This statement may be generalized to include the effect of a shift from spending to saving or from saving to spending by regarding saving as a commodity in whose production a zero proportion of every factor is employed.)

Thus for any given factor, but not for the group, there may be complete reëmployment without increase in investment in the system.

The only hope of avoiding unemployment when factor-economizing technical advance occurs is that the technical change may induce investment, say, in a plant to make a machine which the newly invented process requires.[7] Barring a "pump-priming" effect, the favorable effect will be only temporary.

Three conclusions of considerable significance may be drawn at this stage in the discussion:

1. The Moulton and Bell arguments that price reduction prevents or tends to prevent technical unemployment need qualification.[8]

2. It must not be assumed that, given no change in consumption and saving functions, a constant level of investment will maintain full employment.[9]

[6] As a special case: if only one factor is displaced it will suffer *added* unemployment if the new demand is for goods produced *in any degree whatever* by any other factor. Note Neisser's error, *op. cit.*, pp. 54-56.

[7] Of course I do not mean investment in the machine itself. In an open system, reduction in price of a commodity may stimulate export or check import of that commodity. Increase in domestic employment secured in this way, however, is not true reëmployment, but only a means of shifting the unemployment to foreign countries.

[8] H. G. Moulton, *Income and Economic Progress* (Washington, Brookings Inst., 1935), p. 119. My criticism is of course directed at this remark only, not at other observations by Mr. Moulton concerning the effects of price reduction.

Spurgeon Bell, *Productivity, Wages, and National Income* (Washington, Brookings Inst., 1940), p. 182.

[9] *Cf. Saving, Investment, and National Income*, T.N.E.C. monog. no. 37, p. 68; "A rate of current investment equal to the current rate of saving leaves the flow of purchasing power unbroken, and maintains the level of employment, consumption, and national income."

The analysis of a model in which the state of the arts is taken for granted must not be applied to a system in which the state of the arts is changing.

3. It follows that technological advance during a prosperity period may be a deflationary force which ushers in a recession.

As a final word, it should be noted that, in discussing the historical problem of technological change and the maintenance of employment, emphasis must not be directed exclusively—or even primarily—to the expansion of investment. Either an increase in investment, with a given consumption function, or an increase in consumption (a shift in the function) with a given propensity to invest, will increase employment. Surely historically, in the United States and elsewhere, it has been by a rise in the standard of living even more than by increase in the rate of investment that the effect of technological advance upon employment has been counteracted.[10]

EVERETT E. HAGEN

Washington, D.C.

The Concept of Technological Unemployment: A Reply to Mr. Hagen's Criticism

There is no basic theoretical quarrel between Mr. Hagen and me. He shows that the replacement of labor by the machine *may* reduce the utilization of existing equipment, because it *may* increase the volume of speculative balances and *lower* the size of the current money flow. Throughout my paper I assumed, in accordance with most of the former writers on the subject of technological unemployment and for the sake of the argument, that "Say's Law" was in force, *i.e.*, that an appropriate money flow was *maintained.* Since Mr. Hagen admits that this is possible (second paragraph, second sentence of his note), my analysis seems to cover wider grounds than his. Moreover, one fundamental proposition of short-run price theory, *viz.*, that supply curves are positively inclined, is needed by Mr. Hagen as well as by me, although Mr. Hagen seems to dispute that. Were the supply curves horizontal, then total unemployment (voluntary and involuntary) in the Keynesian system (which underlies Mr. Hagen's argument) could be eliminated by the simple device of increasing the stock of money. Surely, unemployment existing solely because of the inadequacy of the monetary institutions could not be called technological according to customary terminology.

Mr. Hagen misjudges the relative positions of our theoretical arguments because he seems to have difficulty in recognizing a theoretical idea if it is couched in terms he is not accustomed to. Witness his footnote 4: "Neisser's argument that the quantity of fixed capital is of peculiar importance . . . in limiting employment, seems totally untenable. . . . Certainly the most that can be said is that bottlenecks may develop in one type or another of fixed

[10] The importance of giving shifts in the consumption function a place in one's analysis has been insisted upon by Paul A. Samuelson.

capital as well as one type or another of circulating capital or of human skills. . . ." Of course, I do not deny that bottlenecks can develop also in the field of human labor, in which case we experience "technological unemployment of machinery." But why does it follow that the limitations of the stock of fixed capital are unimportant? Or does Mr. Hagen conclude that, because both bottlenecks in fixed capital and bottlenecks in labor are theoretically possible cases, the former cannot be of significance for explaining unemployment of labor? As pointed out in my article (pp. 64-65) the original Walras system with fixed technical coefficients has meaningful solutions only if these coefficients are "adjusted" to each other; otherwise unemployed surpluses of *some* factors of production may arise. Changes in the size of such coefficients are likely to throw them out of gear. Since such changes (if pertaining to equipment) and "technological progress" are synonyms, it seems appropriate to call unemployment resulting from them "technological unemployment."

The real difference between Mr. Hagen and me originates in the difference in our mental pictures of the present economic system. Whether one deals with an economy of the type of the Chinese economy around 1900, where the peasant worked a small plot with a hoe, or with a modern industrial system, the volume of employment, according to Mr. Hagen, would always be governed by the same factor: the current volume of investment per time unit. But suppose the American economy could be suddenly converted into a system of semi-automatic plants, similar to a modern electricity plant based on water power and made of material of practically unlimited durability, would the number and size of these plants (the "quantity of fixed capital") be unimportant for the volume of employment? Could a given number of such plants, of a given size and operating with a given technique, absorb any supply of labor, *however large,* provided only the current volume of investment is sufficiently increased?[1] I cannot but answer this question in the negative. It seems to me that movement toward such an industrial state has been the main feature of the capitalist development during the last 150 years.

Two further criticisms of Mr. Hagen's, in footnotes 5 and 6, do not bear on the general argument and are based on misunderstandings. As to footnote 5: my concept of working capital is the usual one, stock of wage goods, expanded to "stock of all goods in process." At no place do I identify it with technical equipment. And when, to avoid injustice to Carnes and Sidgwick, I discussed the consequence of a fall in the value of working capital, I considered the terminological distinction between working capital and value of working capital sufficiently clear. I am sorry to learn that it has confused Mr. Hagen.

As to footnote 6: Mr. Hagen overlooks that I discussed differences in the proportion of factors employed under the explicit assumption, introduced for the sake of the argument, that the supply curves are horizontal over a

[1] This investment would, in subsequent periods, increase the number and size of plants; see Section VII of my article. For Mr. Hagen's argument this is irrelevant.

certain range. This implies an unutilized surplus of the "other factor" while Hagen in his approach assumes the absence of such a surplus.

HANS NEISSER
